RESUME

La campagne océanographique trans-Pacifique: Alize 2 a été réalisée entre le 3 janvier et le 5 mars 1991 depuis Panama jusqu'à Nouméa à bord du N.O. NOROIT. Au cours de cette traversée du Pacifique le long de l'équateur, cinq radiales méridiennes ont été effectuées entre 2°30' N et 2°30' S. Des mesures ont été faites le long de la route du navire et au cours de 113 stations hydrologiques. Les opérations en station comprenaient principalement un trait de bathysonde et des prélèvements d'eau à 12 niveaux à l'aide d'une rosette de bouteilles à fermeture télécommandée. Ces prélèvements ont permis les dosages de salinité, oxygène dissous, sels nutritifs dissous (nitrates, nitrites, phosphates et silicates) et ceux des rapports isotopiques concernants le carbone 13 et l'oxygène 18. Des filtrations d'eau ont été faites sur les prélèvements pour déterminer la teneur en chlorophylle et mesurer l'épi-fluorescence. Des prélèvements pour le dosage des chlorofluorométhanes furent faits lors du premier leg seulement. Vingt-neuf bouées dérivantes furent déployées au cours de la campagne. Des sondes de température ont été lancées lors des parcours de liaison entre Tahiti et l'équateur et entre la fin de la dernière radiale à 165°E et Nouméa. Vers 170°W, à l'équateur, deux mouillages ont été relevés et remplacés; il s'agissait : d'un mouillage de surface ATLAS avec chaîne à thermistances et d'un mouillage de sub-surface équipé d'un courantomètre acoustique. Le long de la route du navire, la pression partielle de CO₂ dans l'air et dans l'eau, la température et la salinité de l'eau ont été enregistrées en continu. Le navire était équipé d'un courantomètre acoustique à effet Doppler qui, couplé au système de positionnement GPS, a permis de mesurer les courants absolus de la couche 0-300 m. Des observations météorologiques ont été faites à intervalle de temps régulier; la mesure du rayonnement solaire incident a été faite pendant toute la durée de la campagne. Enfin deux appareillages nouveaux ont été testés, ils concernent d'une part la mesure de la pression de CO₂ dans l'eau et d'autre part la mesure de la production primaire "in-situ". Cette opération, réalisée sur le navire océanographique NOROIT mis à notre disposition par l'IFREMER, a été financée par le CNRS et l'ORSTOM. Ce document présente les conditions de réalisation et les premiers résultats des mesures.

ABSTRACT

ALIZE2 is a trans-equatorial Pacific cruise on board the French R.V. NOROIT from Panama on January 3 1991 to Noumea on March 5 1991. The route followed was mainly along the equator with five 2°30'N-2°30'S meridional sections and a port-of-call in Tahiti. The research vessel, a unit of GENAVIR was provided by IFREMER with grants from CNRS (INSU) and ORSTOM. Data are comprised of continuous measurements of near-surface parameters and 113 hydrological stations in the upper 2000 meters.

The stations data include temperature, salinity and dissolved oxygen profiles from CTDO casts and samples from a 12-bottle rosette. The water sampled has been analyzed for salinity, dissolved oxygen, dissolved inorganic nutrients (nitrates, nitrites, phosphate and silicate), as well as isotopic ratios for carbon-13 and oxygen-18. Water was filtrated for chlorophylle-a concentration and epi-fluorescence estimation. The chlorofluoromethane F12 (CCl_2F_2) was also analyzed between Panama and Tahiti. Twenty-nine surface drifters were deployed during the cruise close to the equator. XBTs were launched during the meridional transects between Tahiti and the equator (150W) and the equator (165E) and Noumea. At the equator, in the vicinity of 170W, two moorings were serviced, one ATLAS surface mooring equipped with a meteorological station and a thermistance chain, and a subsurface mooring instrumented with a Doppler currentmeter.

Near-surface measurements include carbon dioxide partial pressures in air and sea water, sea surface temperature and salinity from a thermo-salinometer, absolute current profiles in the upper 300 meters from a hull Doppler currentmeter coupled with the GPS positioning unit. Standard meteorological observations have been done routinely, and time series of the incoming short wave radiations are available for part of the cruise. Finally, two experimental devices were tested, one for measuring carbon dioxyde in sea water, and the other for in-situ primary production.

I - INTRODUCTION.

Le déroulement de la campagne océanographique ALIZE2 dans l'océan Pacifique équatorial est relaté dans ce document, d'une part, en présentant une description générale des conditions océanographiques et météorologiques rencontrées, d'autre part, en faisant le point des opérations entreprises et des données recueillies et enfin en présentant les premiers résultats.

La campagne ALIZE2 s'inscrit au sein de "TOGA" (Tropical Ocean and Global Atmosphere), une action du *World Climate Research Program* soutenue en France par le *Programme National d'Etude de la Dynamique du Climat*, dont le principal objectif est de préciser les mécanismes interactifs entre océan et atmosphère qui pourraient être, entre autres, la raison de la variabilité interannuelle de l'océan Pacifique tropical. La mission ALIZE2 était destinée à procurer une vision "instantanée" des conditions océaniques, tant physiques que chimiques et biologiques de la bande équatoriale du Pacifique. Elle s'insère aussi dans un ensemble assez lâche spatialement de mesures au point fixe (mouillages, marégraphes), de radiales océanographiques répétées (SURTROPAC, EPOCS, ...) et d'un réseau de bouées dérivantes, mis en place depuis cinq ans.

La campagne ALIZE2 permet d'avoir une vue quasi-synoptique de l'océan Pacifique à l'équateur. Elle succède à la campagne ALIZE réalisée par l'ORSTOM à bord du N.O. Coriolis, en fin 1964 et début 1965 qui avait fourni la première section hydrographique d'un bord à l'autre du Pacifique équatorial (Rotschi et al., 1967). Cette section (Lemasson et Piton, 1968; Colin et al., 1971) a servi de nombreuses fois à illustrer le contraste entre Pacifique occidental et oriental. Récemment, Hisard (1985) a souligné que la première campagne Alize s'était déroulée en même temps qu'un phénomène El-Nino se produisait; la première partie ayant observé les conditions précédant un El-Nino alors que la deuxième se déroulait pendant l'événement chaud de 1965.

La campagne ALIZE2, s'est déroulée à bord du N.O. LE NOROIT; elle résulte d'une coopération entre une équipe CNRS (LODYC-Paris) et plusieurs équipes ORSTOM (groupes SURTROPAC et PROPPAC à Nouméa, équipe ORSTOM-LODYC à Paris) avec une participation d'IFREMER et de la Météorologie Nationale. Le financement des opérations provient de contrats IFREMER et INSU et d'importantes contributions de différentes équipes ORSTOM. Les opérations effectuées comprennent, d'une part, 113 stations d'hydrologie par bathysonde au cours desquels des prélèvements étaient recueillis pour des analyses de chimie ainsi que 33 profils de température par sonde perdable, d'autre part, des opérations menées le long de la route (courant par un profileur à effet Doppler, météorologie, rayonnement incident par pyranomètre, pression partielle de CO₂ atmosphérique et océanique par absorption infra-rouge, biomasse de phytoplancton, pH des eaux de surface, température et salinité de surface en continu). Une expérience de mesure de pression partielle de CO₂ par colorimétrie a aussi été testée lors de la campagne. Nous avons aussi participé à la maintenance du réseau TOGA de mesures *in situ* de l'océan Pacifique équatorial, d'une part par des lâchers de 29 bouées dérivantes (dont 27 ont pu être positionnées), d'autre part, en permettant la relève d'un mouillage de courantométrie Doppler à (0°, 169°30'E) (responsable R.Weisberg) et la relève d'un

mouillage ATLAS équipé d'une station météorologique et d'une chaîne de thermistances à (0°, 169°30'E) (responsable S.Hayes).

Après cette introduction, ce document comprend cinq parties. La première donne la liste des participants, la deuxième est un aperçu des conditions rencontrées dans l'océan et l'atmosphère lors de la campagne. Les troisième et quatrième parties sont consacrées aux conditions de réalisation des mesures recueillies le long de la route et en station. La cinquième partie présente l'ensemble des illustrations qui sont regroupées en quatre annexes.

II - PERSONNEL SCIENTIFIQUE DE LA CAMPAGNE.

LEG 1: Panama, le 3 janvier - Papeete, le 3 février

Chef de mission: Gilles Reverdin, chercheur au CNRS (détaché au Lamont Doherty Geological Laboratory à New-York)

| John Shanley | PMEL Seattle (USA), technicien (mouillages). |

III - CONDITIONS GENERALES RENCONTREES.

Le long d'une route longeant l'équateur, nous avons réalisé 6 mini-radiales méridiennes au travers du sous-courant équatorial (chacune d'une durée maximale de 48 heures). Ces radiales sont situées à: 96°W (9-10/01), 110°W (15-16/01), 125°W (mesures de courant seulement, 22/01), 140°W (27-28/01), 168°W (17-18/02), 165°E (27-28/02).

Entre les radiales 140°W et 168°W, le navire a fait escale pendant 3 jours à Tahiti, puis est remonté sur l'équateur le long de 149°W. Les données recueillies ne constituent certes pas une vision instantanée des conditions rencontrées. Cependant, elles offrent un aperçu des différences longitudinales au début de l'année 1991.

Une présentation succincte basée sur les mesures de courant et de température et sur les analyses et séries temporelles présentées dans les "Climate Diagnostics Bulletin" (éditeur, Vernon E. Kousky) des mois de février à mai 1991, permet de situer la campagne par rapport à la situation océan-atmosphère rencontrée au début 1991. En moyenne mensuelle, d'après les analyses du FSU (J.O'Brien), les vents correspondent à un régime d'alizés du sud-est au voisinage de l'équateur de 110°W à 180°W un peu plus intense que celui que l'on peut attendre en cette saison. Il semble aussi (du moins, en composant plusieurs cartes mensuelles) que les vents méridiens vers le nord sont plus forts que de coutume. De 180°W à 165°E, les vents moyens sont faibles, mais soumis à une forte variabilité.

Les cartes mensuelles de niveau de la mer, basées sur un petit nombre de stations, suggèrent une anomalie positive au voisinage de l'équateur (soit une thermocline plus profonde) de 160°E à 140°W en janvier et aux voisinages des îles Galapagos en février. Les analyses de la structure thermique, produites par Ants Leetmaa par assimilation de données au sein du modèle aux équations primitives du GFDL, suggèrent une pente de la thermocline (isotherme 20°C) confinée à l'est de 140°W en début janvier 1991 et plus répartie le long de l'équateur un mois plus tard. La coupe de température d'ALIZE2 effectuée au long de 56 jours de route confirme dans ces grands traits cette analyse (notons que certains profils de température et de salinité de la campagne étaient assimilés par le modèle). Dans la couche supérieure de l'analyse du modèle, on constate un gradient de température de 100°W à 180°W. La distribution de température lors de la campagne suggère que le gradient zonal est encore présent à l'ouest de 170°E.

Cette structure se retrouve tout au long de la campagne sur les analyses hebdomadaires de température de surface. Sur l'analyse présentée dans "Climate Diagnostics Bulletin" (20 février 1991), on observe que la température est plus faible à l'équateur qu'à 5°N ou 5°S depuis le voisinage de l'Amérique du sud jusqu'à 180°W. Cette structure témoigne d'un upwelling équatorial encore actif, même si il n'est pas aussi fort que dans les mois qui précédent. Cette divergence est d'ailleurs bien présente sur les trajectoires des bouées déployées lors de la campagne, du moins entre 170°W et 110°W (noter que les trajectoires présentées pour l'ouest de la croisière ne sont pas synoptiques de celles de l'est déployées bien avant). Sur les cartes hebdomadaires de température de surface pour janvier 1991, le front de température au nord de l'équateur présente des ondulations à l'est de 120°W. Ces ondulations étaient associées à d'intenses fluctuations de la vitesse méridienne qui ont été

observées par LE NOROIT lors de sa route vers l'ouest de 96°W à 120°W. Ces fluctuations de la vitesse méridienne ont aussi été observées au niveau supérieur du mouillage de 110°W.

Les moyennes journalières de vent, de température, d'immersion de la thermocline et éventuellement de courant, provenant de divers mouillages au voisinage de l'équateur, nous permettent de préciser dans quelles conditions ont été réalisées les mini-coupes méridiennes. En général, les alizés du sud-est étaient plus forts que de coutume en janvier et février sur presque tous les sites avec des fluctuations du vent zonal pouvant atteindre 2 m/s. Les fluctuations méridiennes du vent sont en général plus faibles que celles de la composante zonale du vent, en particulier le long de 110°W, où un effet des ondulations du front thermique sur le vent de surface n'est pas à écarter.

Dans l'est du bassin, la campagne se déroule lors d'une phase d'augmentation de la température de surface, comparable à ce que l'on trouve d'ordinaire (noter cependant l'anomalie froide à l'équateur à 140°W, qui n'est d'ailleurs pas présente à 2°S et l'anomalie chaude très stable le long de 165°E). La radiale de 96°W (9-10/01) se déroule à un moment où le niveau de la mer est particulièrement élevé aux Galapagos. On peut donc s'attendre à une thermocline plus profonde à l'équateur, ce que nous avons observé. Un fort courant de surface vers l'est lui était associé avec une légère remontée de la thermocline au sud de l'équateur.

Lors de la radiale le long de 110°W (15-16/01), on constate également l'existence d'un courant de surface vers l'est (aussi observé sur les enregistrements du mouillage, où il s'est maintenu vers l'est pendant près de 40 jours). La thermocline est aussi anormalement profonde. Le long de 125°W, le 23-24/01, le courant de surface est moins intense et la thermocline a plus tendance à être bombée vers le haut à l'équateur.

Les 28-29/01, lors de la radiale de 140°W, les mouillages indiquent que l'isotherme 20°C est fortement remontée (25 mètres) dans les 15 jours qui précédent, alors que le courant de surface était passé d'est à l'ouest. La composante méridienne du courant est toujours restée faible pour ce mouillage équatorial. Nous avons par contre constaté une divergence méridienne avec un courant méridien de 30 cm/s vers 1°30'N et -30 cm/s vers 2°S (au vu des différentes structures de v lors des sections voisines de 125°W et 149°W, peu d'importance doit être attribué à cette structure).

Le long de 168°W (17-18/02), c'est une thermocline voisine de sa position ordinaire qui est trouvée, alors qu'à 165°E (27-28/02), la campagne s'est effectuée dans une phase d'approfondissement de la thermocline, associée apparemment à des coups de vent d'ouest, qui ont probablement débuté 3 jours auparavant et ont atteint 33 noeuds d'après les enregistrements du bord lors de grains le 27/02. D'après le mouillage équatorial, le courant qui portait à l'ouest à la mi-février, était en train de se renverser pour porter à l'est dans les jours qui ont suivi la radiale. On notera d'ailleurs que, lors de la radiale, le maximum de courant portant à l'ouest se trouvait en subsurface autour de 70-80 mètres.

IV - MESURES EFFECTUEES EN ROUTE.

A - Mesures des courants à l'aide d'un profileur acoustique.

Un profileur de courant acoustique à effet Doppler (ADCP) a été installé sur LE NOROIT en Novembre 1990, à l'initiative de l'ORSTOM. Il s'agit d'un modèle RDVM-150, fabriqué par RD Instruments et fonctionnant à 153 kHz. Le transmetteur est placé à la base du puits Martinais du navire, 15m en arrière de la proue à tribord, à 4m sous la flottaison. L'ADCP est interfacé par liaison synchro 1/1 au gyrocompas du bateau. L'acquisition des données est assurée par un micro-ordinateur Compaq 286e. Les positions du navire fournies par le système GPS sont transmises par l'intermédiaire de la centrale de navigation NALNO et stockées avec les mesures ADCP. Les détails de l'acquisition et du traitement des mesures sont donnés par Eldin (1991). Les grandes lignes en sont rappelées ci dessous.

Des profils de courant sont obtenus en continu le long de la route et pendant les stations de la campagne ALIZE 2. Les paramètres d'acquisition utilisés sont les suivants:

- longueurs de bin et d'impulsion: 8 m
- intervalle de récupération: 4 m
- moyenne d'ensemble: 5 minutes.

Dans ces conditions, un profil de vitesses zonale et méridienne est obtenu toutes les 5 minutes, avec une résolution verticale de 8m; l'erreur aléatoire sur chaque mesure est inférieure à 1 cm/s. La profondeur du premier bin est de 16m. En prenant pour critère un seuil de 30% de pings acceptables par ensemble, la portée moyenne de l'ADCP durant la campagne est de 260 m, avec un maximum à 350 m dans les eaux riches du Pacifique Est.

Le traitement des données est effectué à l'aide du logiciel CODAS3, mis au point par Eric Firing et ses collaborateurs (Bahr et al., 1989, 1990). Les profils de vitesse relative sont tout d'abords soumis à des tests statistiques permettant de détecter les niveaux élevés de bruit ou les réflexions parasites. L'étalonnage de l'appareil est effectué suivant la méthode décrite par Pollard et Read (1989) pour chaque arrivée et départ de station. Suite à cet étalonnage, les vitesses relatives sont corrigées par application d'un facteur multiplicatif moyen de 1.003 et une rotation moyenne de -0.3 degré. Cet étalonnage étant basé sur des valeurs moyennes, il peut subsister des sauts de quelques cm/s aux départs et arrivées de certaines stations. Les vitesses absolues de courants sont obtenues par l'intermédiaire de la vitesse absolue d'une couche de référence, calculée par addition des données ADCP et de la vitesse brute sur le fond du navire déduite des positions GPS. Pour réduire le bruit ajouté par l'imprécision sur les positions, la vitesse de référence est lissée par une fenêtre de Blackman de largeur 2 heures. L'erreur finale sur les mesures est estimée à ± 5 cm/s. Cependant, une erreur dans le programme d'acquisition est à l'origine d'un biais systématique de quelques cm/s dans les données du premier bin, lorsqu'un cisaillement important existe dans les 15 bins suivants. Ainsi, à l'équateur, les vitesses zonales du premier bin sont biaisées vers l'Est, de 5 à 10 cm/s.

B - Observations météorologiques.

Les données météorologiques ont été relevées toutes les trois heures et expédiées sur le réseau de la veille météorologique mondiale suivant les standards des messages SHIP de l'OMM. Pendant le premier leg, elles ont également été relevées toutes les heures de jour. Les données de visibilité et de nébulosité sont observées par l'officier de quart et par un scientifique. Les valeurs de température de l'eau, de température sèche et humide de l'air, de pression, de direction et intensité du vent sont lues sur la station POMAR du bord. Jusqu'au 23 janvier, les données du thermomètre humide semblent douteuses, voire complètement fausses. Les choses se sont arrangées après un nettoyage complet; pendant la suite de la campagne, les valeurs de thermomètre à crécelle sont en accord avec celles indiquées par la station POMAR. La mesure de température de mer indiquée par la station POMAR est biaisée (trop chaude de 0.24°C écart-type de 0.09°C) d'après les comparaisons avec la bathysonde à 2 mètres jusqu'à la station 38.

Le rayonnement solaire a été mesuré à l'aide d'un pyranomètre EPPELEY PSP (fourni et installé par les services de METEO-FRANCE). L'appareil, monté sur cardan, était installé sur la barre de flèche bâbord, au sommet d'un pieu qui permettait à l'appareil d'être quasiment dégagé de toute ombre parasite. Un boîtier électronique d'interface, assurait les fonctions de mesure du rayonnement, d'intégration et de transmission des résultats à un micro-ordinateur. La période d'intégration était de 1 minute.

Par vent arrière, la suie de la cheminée avait tendance à se déposer sur le capteur, de même, après une période de vent fort, le capteur était recouvert d'une légère couche de sel déposé par les embruns. Il fallait donc le nettoyer quasiment tous les jours lorsque ces conditions se présentaient. Cette pollution a certainement entraîné une atténuation du signal. De plus, l'usure de ce matériel (installé à Brest et ayant donc traversé l'Atlantique en décembre) a conduit à des valeurs aberrantes en fin de legs. Le capteur a été remplacé à Tahiti puis, au début du second leg, certains autres éléments de l'ensemble de mesure. L'état du caisson contenant le système à cardans et supportant le capteur à Nouméa était révélateur des conditions difficiles subies par ce matériel, initialement prévu pour des applications terrestres. Serge Planton a la charge de ces mesures

C - Pression partielle de CO₂.

Au cours de la campagne la mesure de la pression partielle du CO₂ dans l'air et dans l'eau a été réalisée suivant la méthodologie par infra-rouge. En parallèle, une expérience concernant le développement d'un nouveau type de capteur a été conduite.

1) Mesures infra-rouge.

Ces mesures ont été réalisées à l'aide d'un analyseur de CO₂ Siemens ULTRAMAT 5E, dont le principe de fonctionnement utilise l'absorption du rayonnement infra-rouge par le gaz carbonique. La pression partielle de CO₂ dans l'air était mesurée après dessiccation de l'air prélevé par pompage à 3.5 mètres environ au dessus du niveau de la mer. La pression partielle du CO₂ dans l'eau de surface était mesurée sur l'air

atmosphérique (prélevé de la même façon) après que cet air soit passé dans un équilibrateur, où il acquiert la même pression partielle de CO₂ que l'eau de mer pompée à la surface. L'équilibrage eau/air se fait dans une trompe à eau par où l'eau de mer injectée aspire l'air qui transite par l'équilibrateur. Le rendement de cet équilibrateur a été testé à plusieurs reprises et était en général compris entre 97 et 100%. Les rendements bas étant associés à des débits d'eau insuffisants, une correction a été apportée pour prendre en compte cet effet. L'analyseur était périodiquement contrôlé à l'aide d'une source de gaz étalon à 707 ppm (commercialisée par Alphagaz). Toutes les 9 minutes, le système était alternativement raccordé à l'air atmosphérique et à l'air équilibré (mer). Une mesure a été conservée pour chaque cycle, 4 minutes après commutation. Une mesure de pression située au niveau de l'équilibrateur et identique à la pression extérieure a permis de convertir les indications en ppm de l'analyseur de gaz carbonique en une pression partielle à l'interface air-mer exprimée en microatmosphères. Une correction pour la pression partielle dans l'eau a été introduite pour prendre en compte la différence entre la température de l'équilibrateur et la température de surface de la mer. Les températures de l'air et de l'eau ainsi que les indications de l'analyseur de CO₂, celles d'un fluorimètre, d'un capteur de pression et d'un capteur d'humidité au niveau de la prise d'air, étaient enregistrées en temps réel. Les résultats finaux ont été lissés par moyenne mobile sur deux heures. Les analyses sont sous la responsabilité de Yves Dandonneau.

2) Etude de faisabilité d'un capteur chimique à fibres optiques.

Un nouveau type de capteur de la pression partielle de CO₂ est en cours de mise au point (LODYC en collaboration avec LGE/Paris VII) avec pour objectif son implantation sur une bouée du type BODEGA (voir annexe 1). L'opportunité a été saisie de pouvoir tester le capteur "en milieu océanique" c'est à dire embarqué sur un navire qui prélève en continu l'eau à la surface de l'océan. Le capteur a été monté en parallèle avec le dispositif de mesure par infra-rouge. Le principe du capteur repose sur la mesure de la variation de densité optique d'un colorant dont l'absorption est une fonction de la pression partielle de CO₂ dans la solution dans laquelle il est dilué. Cette solution est en contact avec l'eau de mer au travers d'une membrane semi perméable au CO₂. Les mesures d'absorption sont faites par spectrophotométrie à trois longueurs d'onde, les liaisons entre la cellule de mesure et le spectrophotomètre sont faites par fibre optique. Les essais effectués pendant la campagne ont permis de faire le point sur différents problèmes posés par le capteur, en particulier: le débit d'eau dans la cellule, la stabilité mécanique du spectrophotomètre et la tenue mécanique de la cellule.

Une bonne corrélation est observée entre le signal du capteur et la mesure infra-rouge (voir figure ci-dessous). Le dépouillement quantitatif de cette corrélation n'a pu être poussé plus loin, un étalonnage complémentaire du capteur devant être fait à posteriori au laboratoire. Cette étude de faisabilité est tout à fait encourageante; elle a permis de définir des modifications, en cours d'implantation à ce jour (sur le spectrophotomètre et la cellule). Ces mesures sont faites sous la responsabilité de L. Merlivat.

D - Température et salinité de surface.

Nous avons prélevé un échantillon d'eau de mer toutes les 3 heures à partir du 08/01 pour estimer la salinité de surface. Notons que les mesures de température faites sur le circuit d'arrivée d'eau mis en place pour la mesure de la pression partielle du CO₂ dans l'eau de mer sont systématiquement plus fortes que les mesures de l'eau de mer à cette immersion, telle qu'elle nous est donnée par la bathysonde lors des stations. Lors du premier leg, nous avons relevé la température de mer indiquée par la station POMMAR, de jour, toutes les heures et de nuit toutes les 3 heures. Cette température est mesurée à l'entrée du circuit de refroidissement des machines et est aussi plus élevée que la température de la mer donnée par la bathysonde (de 0.24°C).

Un thermosalinographe a été installé à l'escale de Papeete, il a permis d'obtenir des mesures de température et salinité de surface pendant tout le deuxième Leg, à une cadence de 5 minutes (du 8/2/91 02:44, 149.5W-17.2S au 6/3/91 01:57, 166.6E-22.3S). L'appareil utilisé était le modèle SBE-21 de la société SEA-BIRD, avec acquisition sur micro-ordinateur. Le niveau de prélèvement était à 3.5m de profondeur, et le débit d'eau dans les capteurs de 4.5 l/mn. Il s'agit du circuit d'arrivée d'eau mis en place pour la mesure de la pression partielle du CO₂. Jusqu'au 20/2/91 08:54, les positions du navire étaient introduites manuellement toutes les deux heures et interpolées linéairement aux instants des prélèvements. Après cette date une acquisition automatique de la position du navire a été mise au point. La température donnée par le thermosalinographe est supérieure en moyenne de 0.31°C (avec un écart quadratique moyen de 0.06°C) à celle donnée par la bathysonde au même niveau.

E - Profils thermiques verticaux (XBT).

Lors du premier leg, nous souhaitions compléter les sections d'hydrographie par des profils de température obtenus par sondes perdables XBT. Malheureusement, nous n'avons pu les effectuer, le système d'acquisition dont nous disposions était hors d'usage. Lors du deuxième leg, des tirs XBT ont été effectués, entre Tahiti et l'équateur (8/2/91 03:23, 149.5W-17.2S au 11/2/91 20:15, 149.8W-1.2S), et de l'équateur à Nouméa (28/2/91 11:20, 164.5E-3.1S au 4/3/91 18:32, 167.0E-21.3S), à une cadence d'environ un tir par degré de latitude. Les sondes Sippican utilisées étaient de deux types, T6 (16 tirs) et T7 (17 tirs, dont un raté), les premières atteignant une profondeur de 450m, et les secondes 700-800m. Les profils thermiques ont été enregistrés à l'aide d'un système PROTECNO, et transmis en temps réel par une balise Argos. Le logiciel utilisé a été mis au point par l'ORSTOM (P. Rual) et CLS-ARGOS. Le décodage et le traitement des données sont décrits dans Langlade et al.(1989).

F - Bouées dérivantes déployées.

Au cours de la campagne, des bouées dérivantes de trois types différents ont été déposées à la mer. Il s'agit d'une part de bouées françaises de type BODEGA, d'autre part de bouées américaines du type TRISTAR et MINISTAR.

1) Bouées dérivantes BODEGA.

Ces bouées font partie d'un ensemble de 50 bouées développées au LODYC en coopération avec l'IFREMER. 13 de ces bouées ont été déployées pendant cette campagne. La bouée comprend : un petit corps de surface où se trouve l'électronique, une petite thermistance, les piles et l'émetteur ARGOS permettant la transmission des données et la localisation par les systèmes embarqués sur satellites, une flottabilité en subsurface placée à environ 2 mètres de la surface et une ancre flottante lestée centrée à 15 mètres d'immersion. Les différents éléments sont reliés par un câble électro-porteur armé sur lequel sont insérées 5 thermistances. Différents modèles de bouées ont été comparés afin de s'assurer que pour les bouées BODEGA, l'erreur sur la dérive n'excédait pas 3 cm/s dans les conditions d'emploi du Pacifique intertropical.

Treize bouées ont été déployées lors de ALIZE2. La bouée 1629 a très rapidement cessé d'émettre une fois à la mer. Les 12 autres bouées dérivaient encore 6 mois après leur lâcher. Toutefois, de nombreuses thermistances n'ont pas fonctionné, soit juste après le lâcher (1620) soit plus tard. Le taux de perte reste semblable à celui d'expériences antérieures. Il y a eu en particulier de nombreuses pertes pour les deux premières thermistances qui sont situées dans la partie supérieure du câble soumise aux plus fortes flexions.

| Site du lâcher | i.d. | Date du lâcher | Mise à zéro | Remarques |

¹ Les indications de présence d'ancres flottantes sont basées, tant sur un capteur qui indique la verticalité de la bouée de subsurface que sur des considérations sur le cycle diurne de la température aux différents niveaux échantillonnes. Pour ces bouées, le diagnostic est établi au 30 avril 1991.

2) Autres bouées dérivantes.

16 flotteurs fournis par Peter P. Niiler ont été déployés au cours de la campagne: douze d'entre eux étaient des bouées TRISTAR dont les câbles étaient équipés de 3 thermistances, quatre d'entre eux étaient des bouées MINISTAR où seule la température à l'intérieur de la bouée de surface est mesurée. 15 ont été correctement localisés après déploiement. Les coordonnées des lâchers sont les suivantes:

| Bouée | Site du lâcher | Date |

V - OPERATIONS REALISEES EN STATION.

A - Mesures avec la bathysonde.

La bathysonde utilisée était une Neil-Brown Mark III. La plupart des profils ont atteint 1000 db, les données étant le plus souvent acquises à partir du premier mètre. Mais, les stations suivantes du premier leg ont atteint 2000 db: 3, 5, 7, 11, 14, 16, 18, 20, 22, 24, 28, 33, 34, 36, 38, 40, 42, 44, 46, 48, 51, 53, 57, 61. Lors de la station 43, réalisée au voisinage de la station 42, la bathysonde n'est descendue que jusqu'à 400 db. Les pertes de données sont peu importantes pour les descentes qui ont été traitées (et résultent de l'application d'un contrôle de qualité pour les forts gradients verticaux peut-être un peu trop sévère). Notons juste que la salinité n'est pas bonne pour la station 7 de 569 à 576 db et la station 14, de 846 à 859 db. L'oxygène n'est pas correct au-dessus de 60 db lors de la station 12 et au-dessus de 40 mètres lors de la station 46.

1) Les conditions de calibration de la bathysonde.

Cette calibration de la sonde s'appuie principalement sur les calibrations à terre (Laboratoire de Métrologie de l'IFREMER) en température et pression et sur les prélèvements en mer pour l'étalonnage de la salinité et de l'oxygène. Quelques mesures de température ont aussi été faites en mer, mais nous ne les avons pas utilisées, étant donné l'absence de dérive constatée lors des calibrations. Par manque de temps, il n'a malheureusement pas été possible de faire l'étalonnage post-campagne de P et T avant la mission SUZIL d'avril 1991. Nous nous sommes donc appuyés sur les calibrations faites à l'issue de la campagne précédente en avril 1990. Lors de la calibration faite à la fin de la campagne SUZIL à la fin juin 1991, il s'avère que les dérives en température n'excèdent pas 0.001°C en-dessus de 5°C . La dérive à 0°C est plus importante (0.003°C), mais il n'est pas sûr qu'elle soit intervenue lors de notre campagne. La dérive du capteur de pression entre les deux étalonnages s'avère indépendante de la pression et est juste recalée en ajustant la pression du pont à 0.

2) La calibration de la bathysonde en salinité.

La calibration de la sonde en salinité suggère une transition entre les stations 61 et 62 (près de 0.02 en salinité). Il se pourrait aussi qu'il y ait eu une petite transition correspondant à 0.005 à 0.010 en salinité entre les station 51 et 52 (la sonde indique des eaux moins salées après la station 52). Nous n'avons pas pu établir un polynôme satisfaisant pour ce petit morceau de la station 52 et 61 et adoptons la calibration des stations précédentes. De surcroît, les changements de température de bain du salinomètre survenus au voisinage de la station 52 pourraient peut-être être mis en cause (des essais du salinomètre pour des températures de bain élevées doivent être menées prochainement). Nous avons donc traité séparément les stations 1 à 70 et 71 à 113. La calibration est faite par un polynôme d'ordre 1 pour toute la gamme de température. On constate que des biais résiduels subsistent pour certaines couches. Dans la thermocline, la salinité (conductivité) ainsi étalonné est plus élevée que ce que suggèrent les prélèvements. Pour les eaux froides, il s'agit d'un biais dans l'autre sens. Autant l'anomalie de la thermocline s'explique probablement par les forts gradients rencontrés dans cette région et ne suggère pas d'erreur dans la calibration, autant celle des eaux froides (5°C ou moins, soient les échantillons recueillis à des immersions de 1000 mètres et plus) n'est pas satisfaisante. La présence de ce biais suggère qu'une loi non-linéaire régirait mieux l'étalonnage. Nous ne disposons pas d'assez de points pour l'établir. Ce biais qui atteint 0.005 (sonde trop basse) devrait être corrigée par les utilisateurs désireux d'une meilleure précision.

3) La calibration de la bathysonde en oxygène.

La calibration de la sonde en oxygène a donné lieu à plus de difficultés. Il s'avère qu'il faut au moins couper la campagne en trois segments: stations 1 à 70; 71-80; 81-113. Le premier décalage correspond à l'arrêt en escale, mais nous n'avons pas d'explications pour le deuxième. Lors du premier leg, il s'est avéré que l'algorithme utilisé régulièrement au LODYC ne donnait pas de résultats satisfaisants. Ce problème vient de

la gamme des faibles oxygène (la sonde indique alors une valeur trop faible par rapport aux prélèvements). La calibration a été établie en retirant les prélèvements d'oxygène inférieur à 2 ml/l. Nous corrigons ensuite le biais de la sonde par une correction linéaire en-dessous de 1 ml/l. La calibration réalisée n'est pas toujours satisfaisante. On remarquera en particulier qu'il aurait fallu découper le premier leg en plusieurs segments. Malheureusement, le nombre de prélèvements aurait alors été trop faible pour établir un polynôme par régression. Près de la surface, il y a aussi souvent des décroissances qui ne trouvent pas leur contrepartie dans les analyses. Dans les 100 premiers mètres de la colonne d'eau, nous conseillons de recaler les données de la sonde sur les prélèvements.

B - Prélèvements.

Douze bouteilles de 5.7 litres étaient montées sur une rosette General Oceanics (modèle 1015-5). Tous les prélèvements ont eu lieu à la remontée de l'ensemble bathysonde - rosette; la majorité a été réalisée dans la couche euphotique. Le fonctionnement de la rosette n'a pas toujours donné satisfaction (le principal problème était une usure de composants sur un des plateaux). Nous disposions en fait de deux rosettes et il a été possible de confectionner une rosette en combinant la mécanique de l'une avec l'électronique de l'autre. Nous avons quand même souvent souffert de pertes de prélèvements (bouteilles non fermées ou deux bouteilles fermées en même temps, en particulier aux stations 19 , 25 et de 33 à 41, et aux stations 61, 62, 68, 71, 75, 78, 81, 82). Il s'est malheureusement aussi avéré que les bouteilles dont nous disposions étaient fortement polluées en Fréon-11, ce qui a été source de grandes gênes pour les mesures des chlorofluorométhanes.

1) Salinité.

Les prélèvements de salinité ont été effectués lors de toutes les stations (à l'exception de la 70) afin de permettre la calibration de la sonde. Les échantillons étaient analysés dans les 48 heures qui suivaient la mesure (un peu plus pour les stations 68 et 69) à l'aide d'un salinomètre PORTASAL. Ce salinomètre de la société GUIDLINE a fonctionné correctement. La pièce dans laquelle il était situé était mal climatisée jusqu'à la station 67 et quand sa température s'élevait au voisinage de la température de régulation du bain, la régulation ne s'effectuait plus. Il a donc fallu plusieurs fois éléver la température du bain qui a progressivement été amenée à 28°C vers l'analyse de la station 53. Lors de ces modifications de température de bain, on ne constate pas de changement important par la comparaison avec les observations de la bathysonde, suggérant que cela n'a pas eu d'effet sur la qualité de la mesure. Dans des cas où la température du bain n'est pas bien contrainte (au voisinage de la température ambiante), la qualité des mesures est moindre. Cela semble le cas de station 52. Le prélèvement 12 (1 db) de la station 4 et les prélèvements 11 (3 db) et 12 (30 db) de la station 102 sont probablement mauvais.

2) Oxygène.

Des prélèvements pour titration d'oxygène dissous ont aussi été faits à toutes les stations. La mesure se fait selon la méthode de Winkler (Strickland et Parsons, 1972) modifiée pour permettre une automatisation à l'aide d'un Metrohm comprenant un Titroprocesseur 386 connecté à une burette automatique Dosimat 665. La précision de la mesure en mer est de l'ordre de 0.005 ml/l. Lors du premier leg, il y avait pénurie d'eau distillée et il n'a pas toujours été possible d'utiliser d'eau distillée pour faire l'étalonnage de la solution de thiosulfate. Nous pouvons juger du bruit aléatoire du dosage en considérant les duplications survenues quand deux bouteilles se sont fermées au même niveau. Ces valeurs suggèrent aussi des différences atteignant jusqu'à 1%. Quelques prélèvements proches de la surface semblent aussi erronés. C'est le cas des prélèvements 11 de la station 15, 12 de la station 21, 11 de la station 38, 11 de la station 41.

3) Sels Nutritifs.

L'analyse des sels nutritifs a été réalisée à bord à l'aide d'un Autoanalyseur II Technicon. Pour les nitrates de concentration supérieure à 2 micromoles/litre et le phosphate, les prélèvements étaient dosés selon des méthodes classiques (Strickland et Parsons, 1972). Pour les nitrates de concentration inférieure à 2 micromoles/litre et pour les nitrites, la méthode d'analyse "haute sensibilité" décrite par Oudot et Montel (1988) a été utilisée. La ligne de base est obtenue avec de l'eau de mer synthétique de salinité 35 usp, préparée avec de l'eau bi-distillée et du NaCl haute pureté. L'Autoanalyseur ayant été endommagé pendant son transport, l'analyse des sels nutritifs n'a pu commencer qu'à la station 7. La précision des mesures correspond à notre attente sauf pour les silicates pour lesquels elle est de quelques micromoles/litre. Les analyses sont sous la responsabilité de Martine Rodier.

4) Biomasse de phytoplancton.

Des échantillons de 100 ml pour analyse de la chlorophylle a totale furent prélevés sur filtres GFF à 111 stations, à tous les niveaux de 0 à 160m. En outre, à toutes les stations situées sur l'équateur (soit 48 profils), la chlorophylle contenue dans les fractions de taille supérieure à 1 et à 3 micromètres fut récoltée sur des filtres Nucléopore (échantillons de 260 ml). Le même dispositif a été utilisé pour mesurer la chlorophylle totale à l'aide de filtres en fibre de verre GFF et la chlorophylle contenue dans les fractions supérieures à 1 et à 3 micromètres récoltée sur filtres Nucleopore. Aux mêmes prélèvements, des échantillons de 60 ml destinés aux comptages au microscope à épifluorescence furent filtrés sur Nucleopore noirs de 0,2 micromètre après fixation au glutaraldehyde (concentration finale 1%). Tous les filtres furent immédiatement stockés au congélateur pour analyse postérieure au laboratoire.

La chlorophylle a été analysée sur des extraits au méthanol à 95 % à l'aide d'un fluorimètre Turner étalonné avec de la chlorophylle a pure Sigma, selon le protocole décrit par Le Bouteiller et al. (Deep-Sea Research, 1991, sous presse). La conservation des échan-

tillons à -20°C, testée lors des missions PROPPAC, n'engendre pas de perte de concentration supérieure à 10 %.

Pour l'énumération des cellules phytoplanctoniques, 200 à 800 cellules ont été comptées par échantillon sur 20 à 80 champs de microscope à l'aide d'un microscope Leitz Dialux 20. Le détail expérimental est décrit par Blanchot et al. (*Journal of Plankton Research*, 1991, sous presse).

Les résultats montrent que les protocoles choisis, les volumes filtrés et le matériel employé convinrent parfaitement aux objectifs fixés: les mesures sont bonnes le plus souvent, et ne s'écartent qu'exceptionnellement des valeurs attendues. Les analyses sont sous la responsabilité respective de Aubert Le Bouteiller et de Jean Blanchot.

5) Mesure du chlorofluorométhane F12 (CCl_2F_2).

De la station 7 à la station 69, des prélèvements relatifs aux chlorofluorométhanes F12 (CCl_2F_2) et F11 (CCl_3F) ont été réalisés, dès la remontée de la rosette sur le pont, à partir de seringues de 100 ml. Les bouteilles Niskin avaient été équipées de ressorts en acier inoxydable au molybdène et les joints toriques avaient été pré-conditionnés (étuvage sous vide à 60°C) afin de limiter la contamination par les fréons absorbés sur le caoutchouc. Malheureusement, une colle-mastic servant de pâte d'étanchéité des soudures plastique du corps des bouteilles, a été responsable d'une importante contamination qui a rendu inexploitable le jeu de données relatif au F11. Deux séries d'échantillonnage des 12 bouteilles à la même immersion ont permis de calculer le rapport F11/F12 de la contamination et de corriger les données F12 de la part de cette contamination (n'excédant pas quelques % du signal). Une fois par jour des analyses ont été réalisées sur prélèvements atmosphériques.

Les analyses ont été réalisées suivant la méthode décrite par Bullister et Weiss (1988) par chromatographie en phase gazeuse (détecteur à capture d'électrons) : les fréons sont dégazés de l'eau de mer (30 ml) par bullage du gaz vecteur (95% argon / 5% CH₄) puis piégés sélectivement à -35°C et enfin séparés et quantifiés par chromatographie. Les concentrations en F12 sont exprimées en ppt (10^{-12}) pour les échantillons atmosphériques ou en pmol/kg (10^{-12} mol/kg) pour les échantillons d'eau de mer. Les teneurs océaniques sont également calculées sous la forme de leurs écarts à la solubilité théorique (Warner and Weiss, 1985). Les calibrations sont faites à partir d'un standard atmosphérique étalonné par rapport à l'échelle de la Scripps Institution of Oceanography. La reproductibilité sur les échantillons marins est de l'ordre de 1% et la précision de la mesure est de l'ordre de 0.05 pmol/kg. La chaîne d'analyse était placée dans un petit conteneur climatisé installé sur la plage arrière du navire.

Lors de la station 64, les analyses de 5 prélèvements n'ont pu être enregistrés. Lors de la station 69 au voisinage de l'atoll de Tikehau, des prélèvements dans des tubes en cuivre ont aussi été recueillis pour permettre l'analyse de l'hélium-3 et du tritium de l'eau de mer. Les analyses sont sous la responsabilité de Chantal Andrié.

6) Isotopes stables (^{18}O de l'eau et ^{13}C du ΣCO_2).

Les prélèvements d'eau réservés à l'analyse des isotopes stables de l'oxygène et du carbone ont été effectués directement à partir des bouteilles de la rosette associée à la bathysonde. Pour chaque niveau, l'échantillonnage a consisté à prélever, d'une part, deux prises identiques d'eau empoisonnée avec 2 ml de solution saturée en chlorure mercurique et conditionnée dans des flacons en verre de 125 ml (échantillons pour l'analyse isotopique du carbone du ΣCO_2), et d'autre part une prise d'eau non traitée conditionnée dans un flacon en verre jaune de 20 ml (échantillon pour l'analyse isotopique de l'oxygène de l'eau).

Ces échantillons sont ensuite traités au laboratoire selon les techniques de préparation classiques : extraction sous vide du ΣCO_2 de l'eau par acidification (Kroopnick , 1974) pour l'analyse isotopique du carbone du ΣCO_2 , équilibration eau-CO₂ à 25°C (Epstein et Mayeda, 1953) pour l'analyse isotopique de l'oxygène de l'eau. Le CO₂ gazeux ainsi préparé est analysé au spectromètre de masse pour en évaluer la composition isotopique δ . Les valeurs de δ sont données avec une précision analytique $2\sigma = 0,01\%$; la reproductibilité analytique sur les mesures d'oxygène 18 et de carbone 13 est de : $\pm 0,05\%$. Les analyses sont sous la responsabilité de Catherine Pierre.

VI PRESENTATION DES RESULTATS

L'ensemble des résultats des mesures effectuées au cours de la campagne est présenté dans quatre annexes à la suite du présent texte.

L'annexe 1 donne le plan de la campagne ainsi que les paramètres mesurés en route (météo, température et salinité de surface, pression partielle de CO₂, XBT). La dérive des bouées pendant 30 jours et la topographie dynamique le long de l'équateur sont également présentées dans cette annexe.

L'annexe 2 présente essentiellement les résultats des observations de courant faites à l'aide du profileur acoustique à effet Doppler. Il s'agit de coupes verticales entre 0 et 400m des composantes zonale (U) et méridienne (V) le long de la route du navire.

L'annexe 3 présente l'ensemble des résultats des analyses effectuées à partir des prélèvements effectués lors des stations hydrologiques. Il s'agit de coupes verticales le long de la route du navire.

L'annexe 4 est une présentation détaillée des données bathysonde et des prélèvements sous forme de liste et de diagrammes.

REMERCIEMENTS.

Nous tenons à remercier les différents organismes qui ont rendu possible cette expérience à savoir, le CNRS (INSU), l'ORSTOM et l'IFREMER qui ont autorisé et financé cette campagne. Le PNEDC a également participé au financement. METEO-FRANCE (S. Planton) a mis un radiomètre à notre disposition. Peter P. Niiler nous a confié les bouées

Tristar et Ministar. Les équipes du LODYC et les équipes ORSTOM de Nouméa ont apporté des contributions essentielles sur les plans humain et matériel. Boer Piton (ORSTOM, Brest) a joué un rôle précieux dans l'organisation de cette campagne, nous l'en remercions sincèrement. L'équipe ORSTOM de Tahiti a généreusement fourni des sondes XBT. J.R. Donguy, B. Campillo de l'ORSTOM ont réussi le montage financier pour l'achat de l'ADCP installé par les équipes techniques de GENAVIR dans des délais très courts grâce à MM Cavarec et Morvan; E. Firing a fourni gracieusement le logiciel d'exploitation de l'ADCP; D. Symonds de la société RDI a répondu avec compétence aux demandes techniques pendant la campagne. Nous remercions C. Rouault, A. Kartavtseff, L. Gamberoni pour leur aide dans la préparation du matériel d'hydrologie. L'équipe SURTROPAC de Nouméa et en particulier Y. du Penhoat nous ont beaucoup aidé pour le transit et autres contingences d'une fin de campagne à Nouméa. Les centres ORSTOM de Tahiti et de Nouméa nous ont fourni une aide logistique précieuse. Nous remercions M. Cane du Lamont Doherty Geological Laboratory qui a autorisé G. Reverdin à participer à cette campagne. Enfin, nous remercions les officiers et membres d'équipage du navire océanographique LE NOROIT pour leur participation active et efficace à toutes nos activités lors de cette campagne.

ANNEXE 1

Contenu:

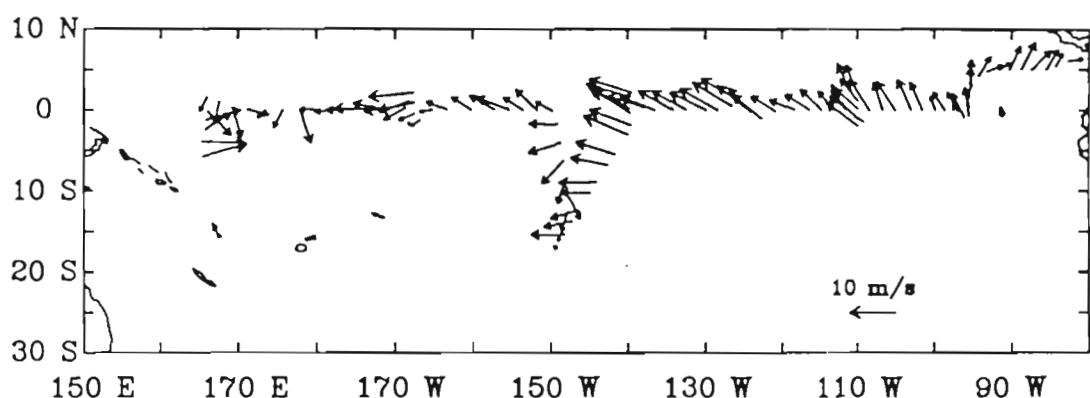

- plan de la campagne
- vent observé
- dérive des bouées pendant 30 jours après leur lancer
- hauteur dynamique le long de l'équateur (surface / 1000 dbar)
- température de l'océan en surface le long de l'équateur (station POMAR)
- température de l'air sec et de l'air humide le long de l'équateur
- rayonnement journalier incident en ondes courtes le long de l'équateur
- pression partielle de CO₂ le long de l'équateur et de radiales méridiennes
- enregistrement du thermosalinographe (leg 2)
- salinité de surface à partir des prélèvements au seau
- résultats du capteur expérimental de pression partielle de CO₂
- coupes verticales de température obtenues à partir des XBT (leg 2)

Résultats de la campagne océanographique Alizé 2

stations CTD, XBT ALIZE2 janvier - mars 1991

vent ALIZE2 janvier - mars 1991

1 mois de derives apres lacher ALIZE2

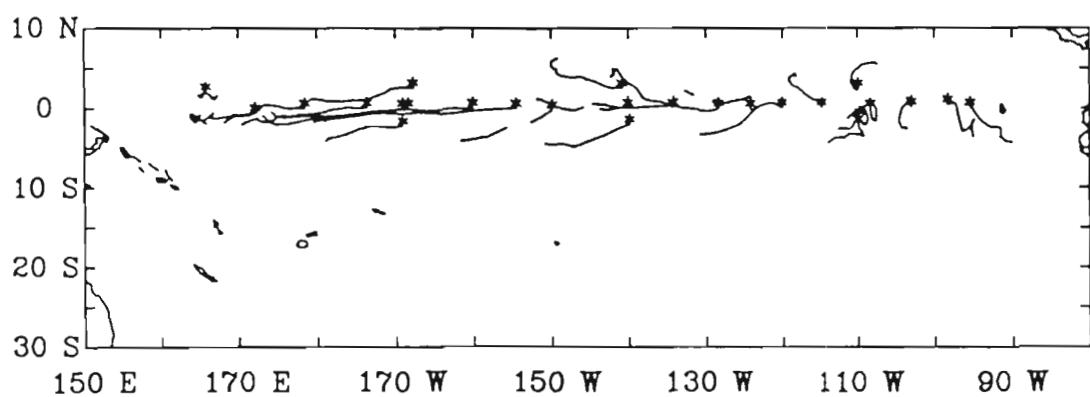

Figure n° 1

Le panneau du haut présente le plan de la campagne ALIZE2. Le panneau du milieu présente le vent moyen sur 12 heures observé à bord du navire le long de sa route. Le panneau du bas montre le trajet parcouru par les bouées pendant les 30 jours suivant leur mise à l'eau (le point de mise à l'eau est figuré par une étoile).

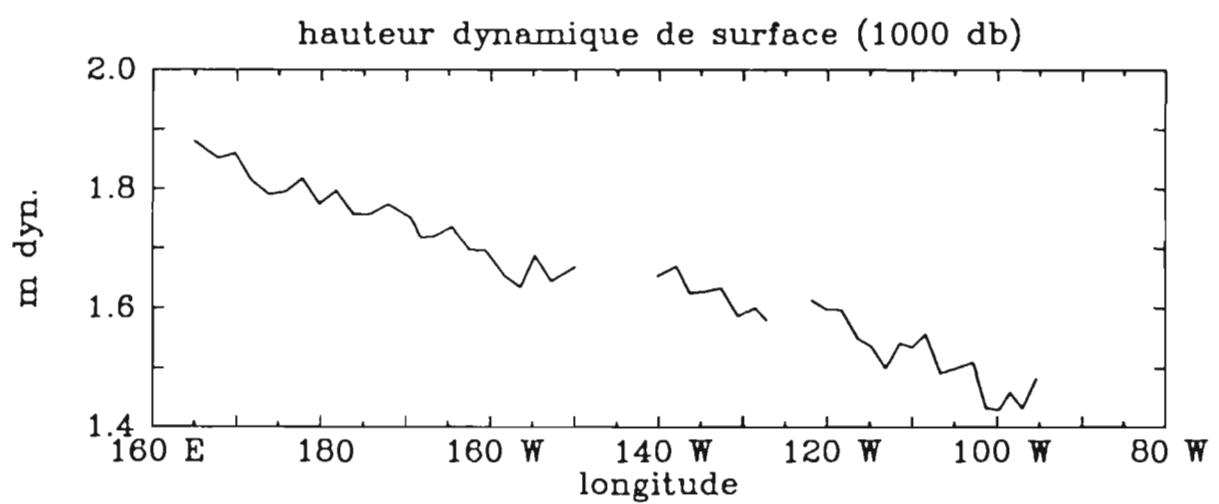

Figure n° 2

Hauteur dynamique de surface calculée par rapport à 1000 décibars avec les données de la bathysonde, le long de l'équateur pendant ALIZE2.

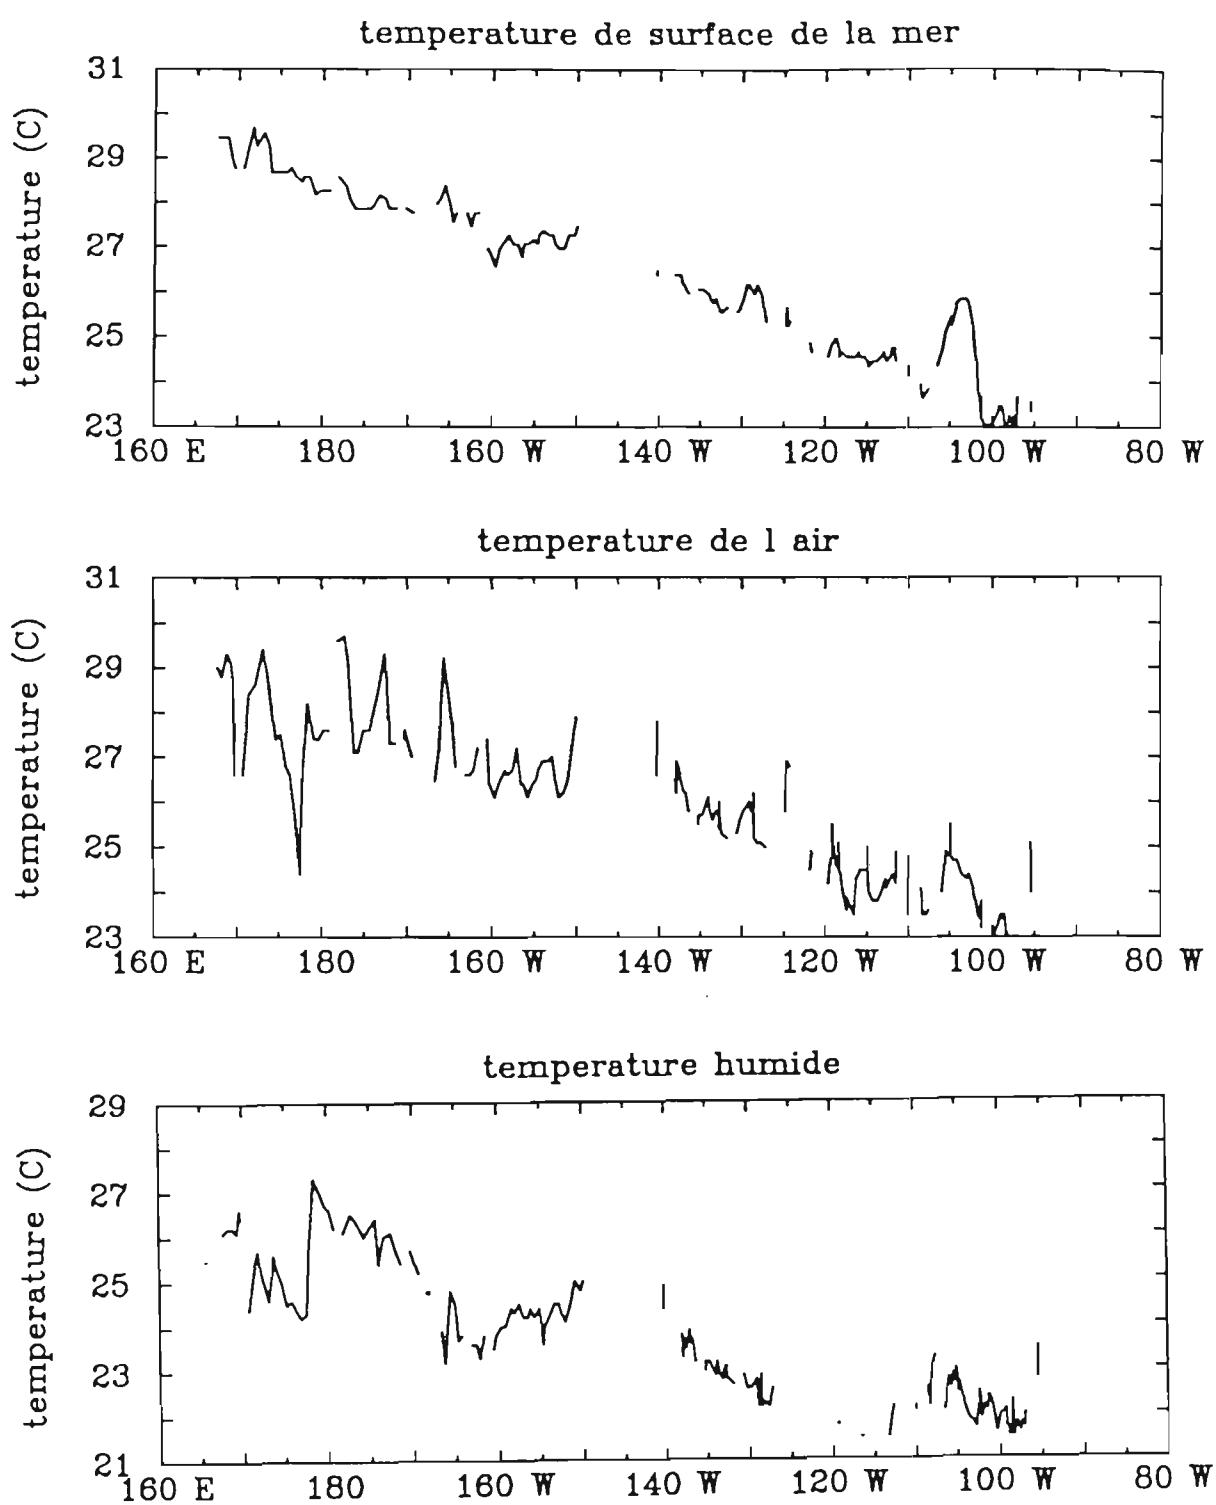

Figure n° 3

Température de surface de la mer (en haut), température de l'air sec (au milieu) et température de l'air humide (en bas) le long de l'équateur pendant ALIZE2.

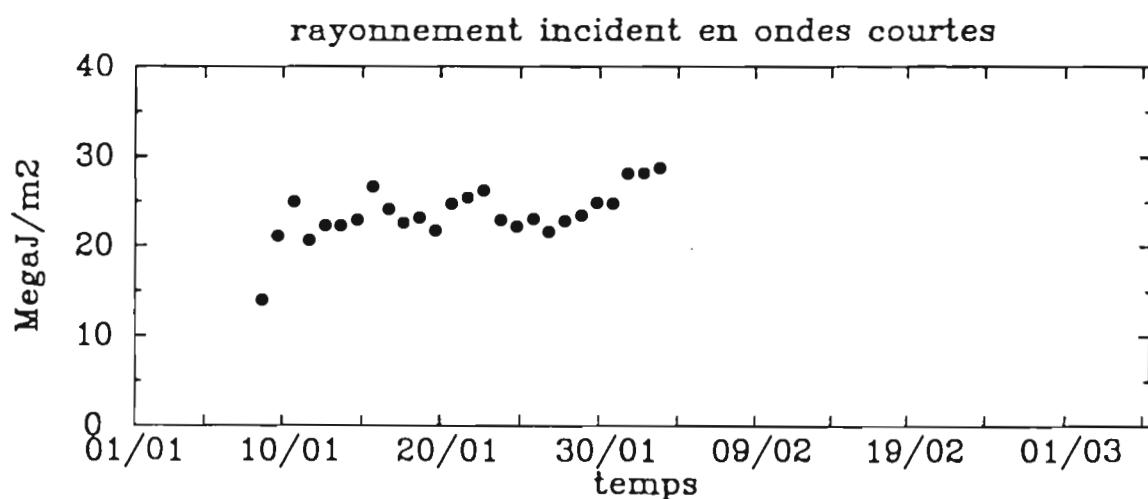

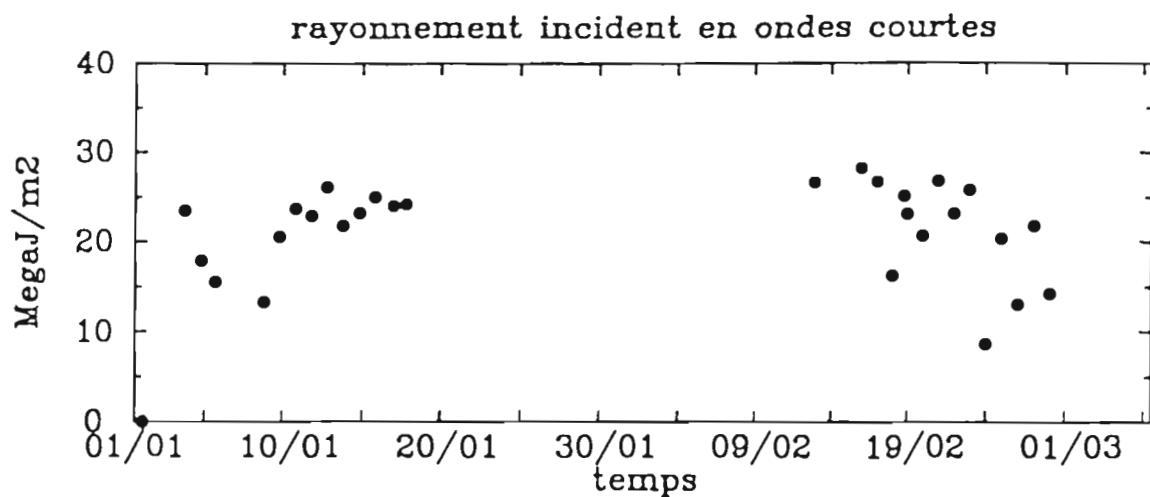

Figure n° 4

Le rayonnement incident en ondes courtes reçu à bord du navire pendant ALIZE2 par un pyranomètre (panneau du haut) et par un intégrateur de lumière (panneau du milieu) est présenté pour chaque jour de la campagne (le flux incident a été intégré du lever au coucher du soleil; les données polluées ont été éliminées). L'intégrateur de lumière est un quantamètre LI510B (société LI-COR, USA) dont le capteur (190M) fonctionnant entre 400 et 700 nanomètres a été calibré avec les données du pyranomètre.

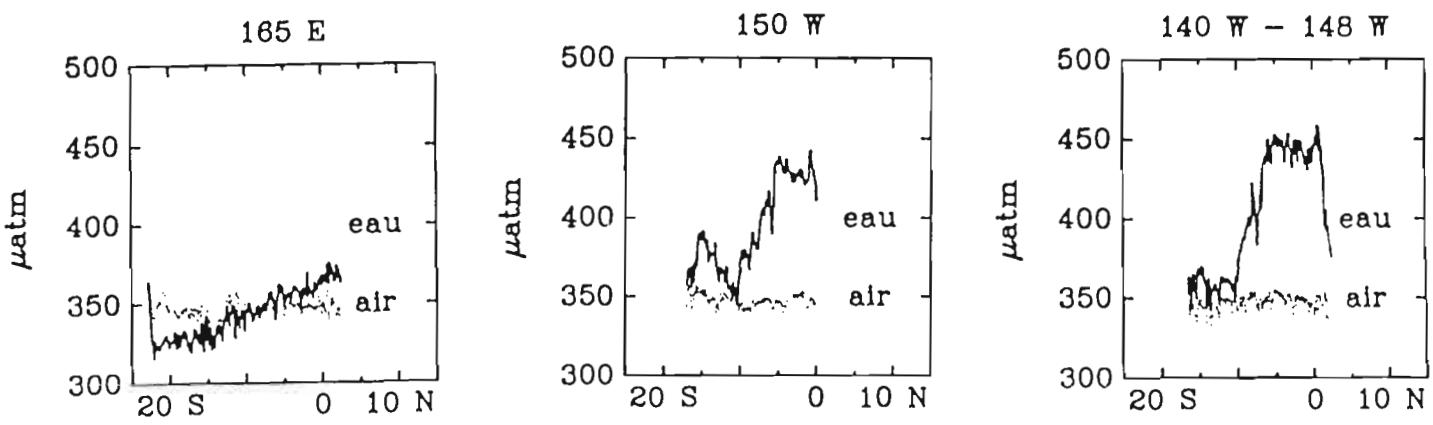

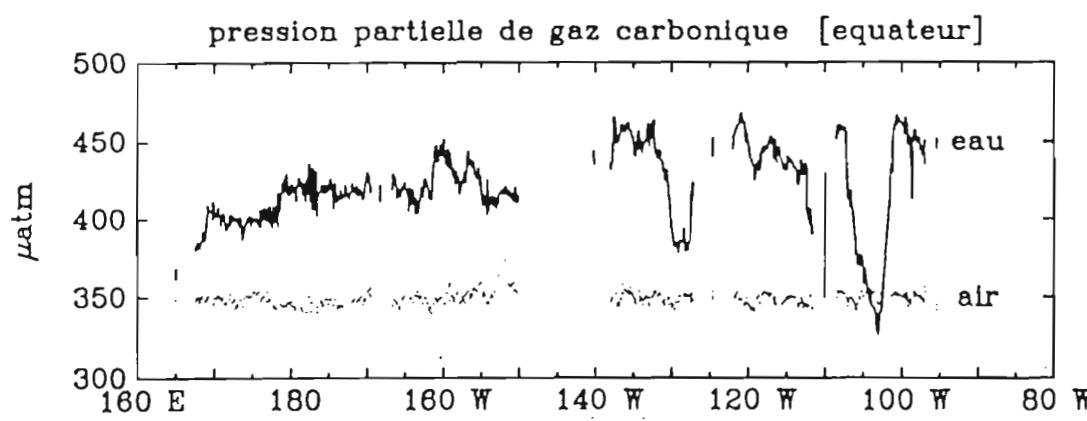

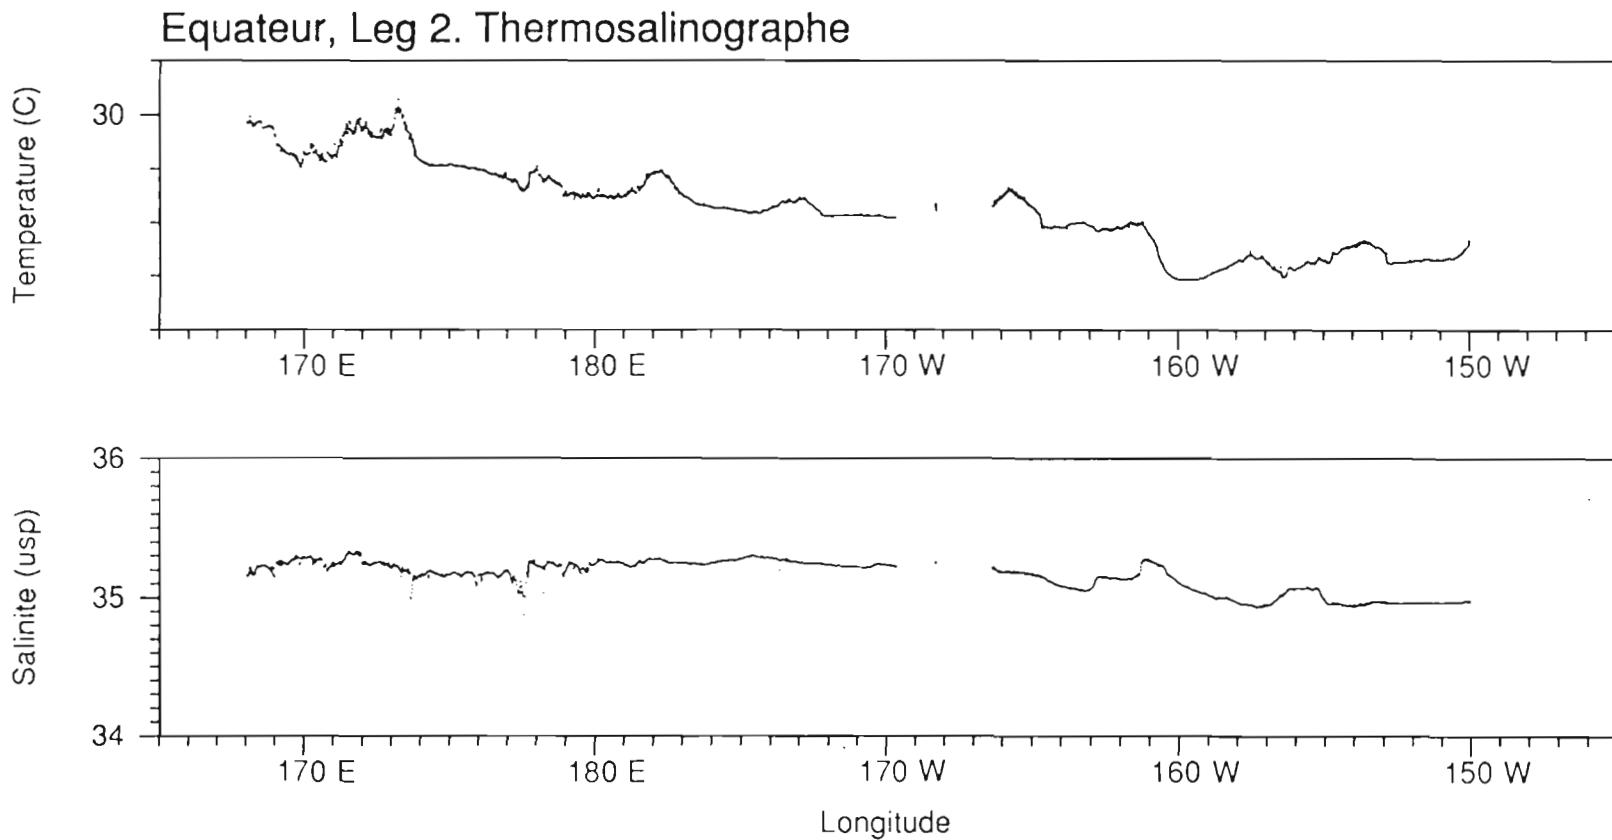

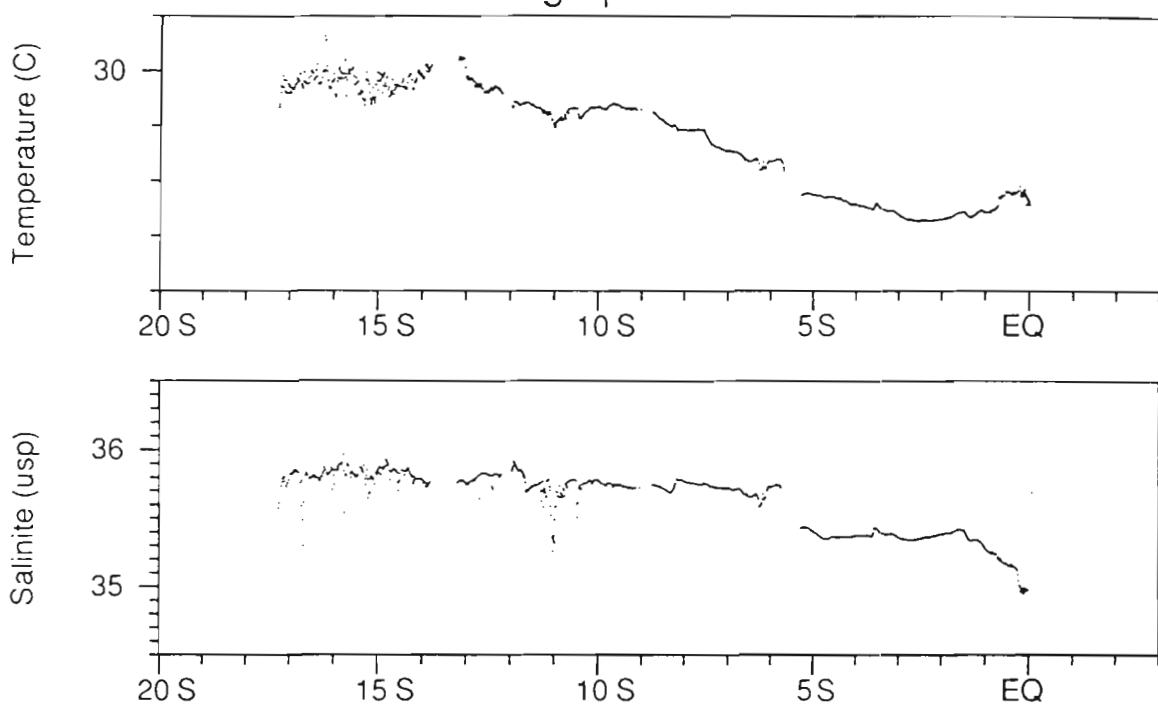

Figure n° 5
La pression partielle de gaz carbonique mesurée dans l'air et dans l'eau à l'aide d'un analyseur infra-rouge est présentée le long de la route du navire, à l'équateur et sur trois sections mériadiennes pendant ALIZE2.

Figure n° 6
Valeurs de température et de salinité enregistrées par un thermosalinographe le long de l'équateur pendant le leg 2 d'ALIZE2.

149W. Thermosalinographe

165E-167E. Thermosalinographe

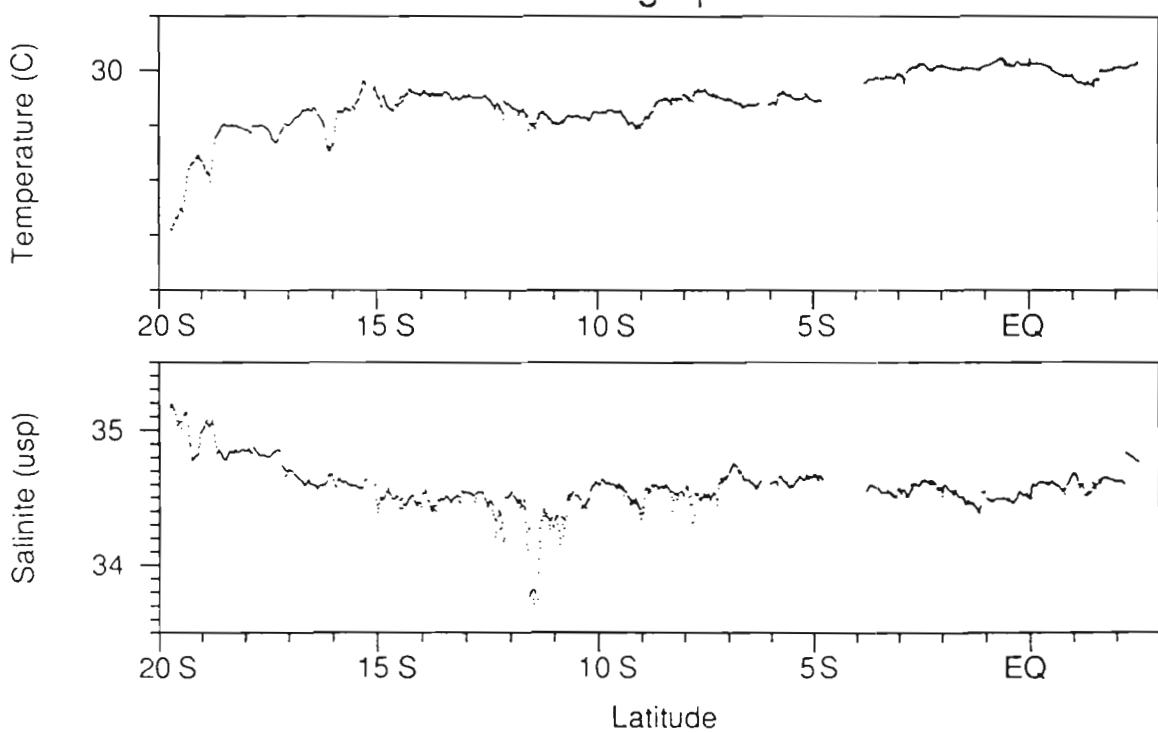

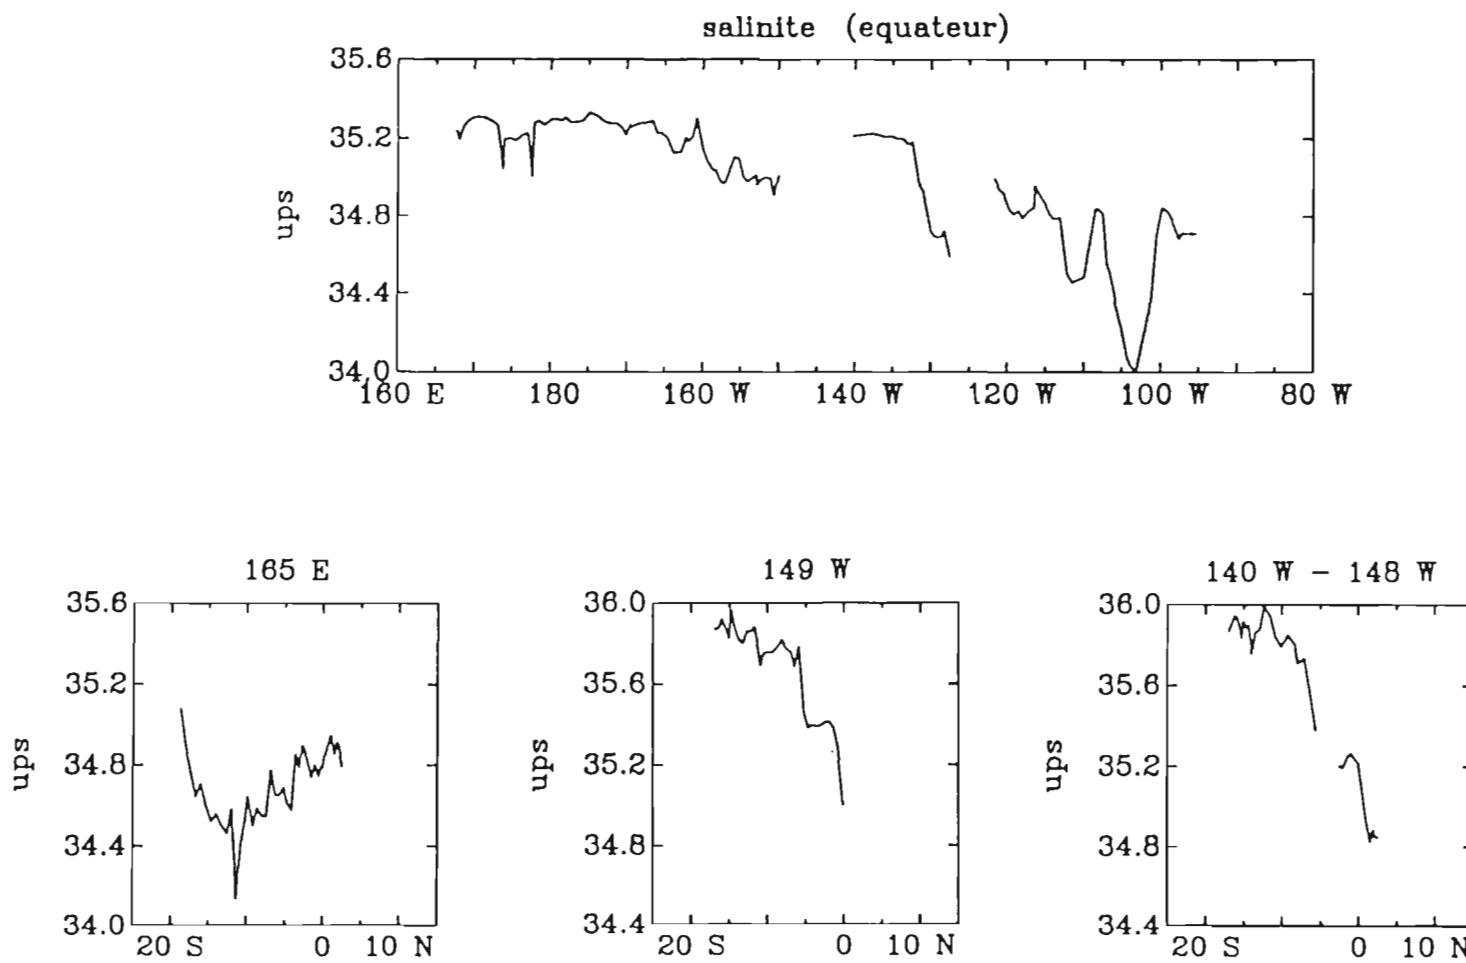

Figure n° 7

Valeurs de température et de salinité enregistrées par un thermosalinographe le long de sections méridiennes au voisinage de 149W et de 165E pendant le leg 2 d'ALIZE2.

Figure n° 8
Salinités de surface prélevées au seu toutes les 6 heures, le long de l'équateur et de trois sections méridiennes pendant ALIZE2.

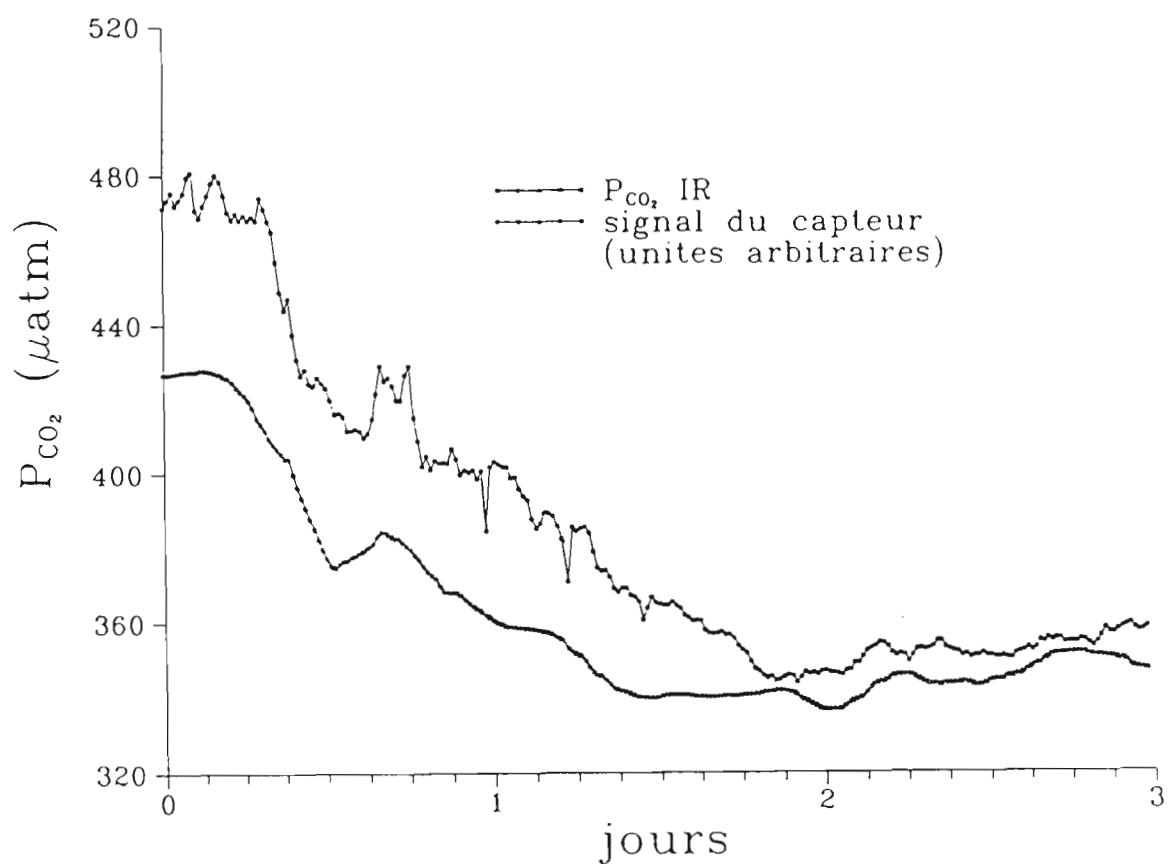

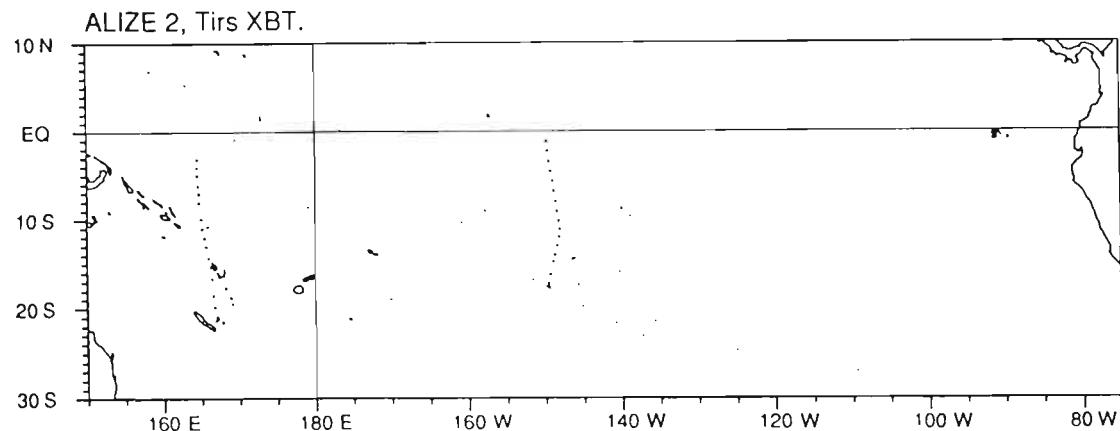

Figure n° 9

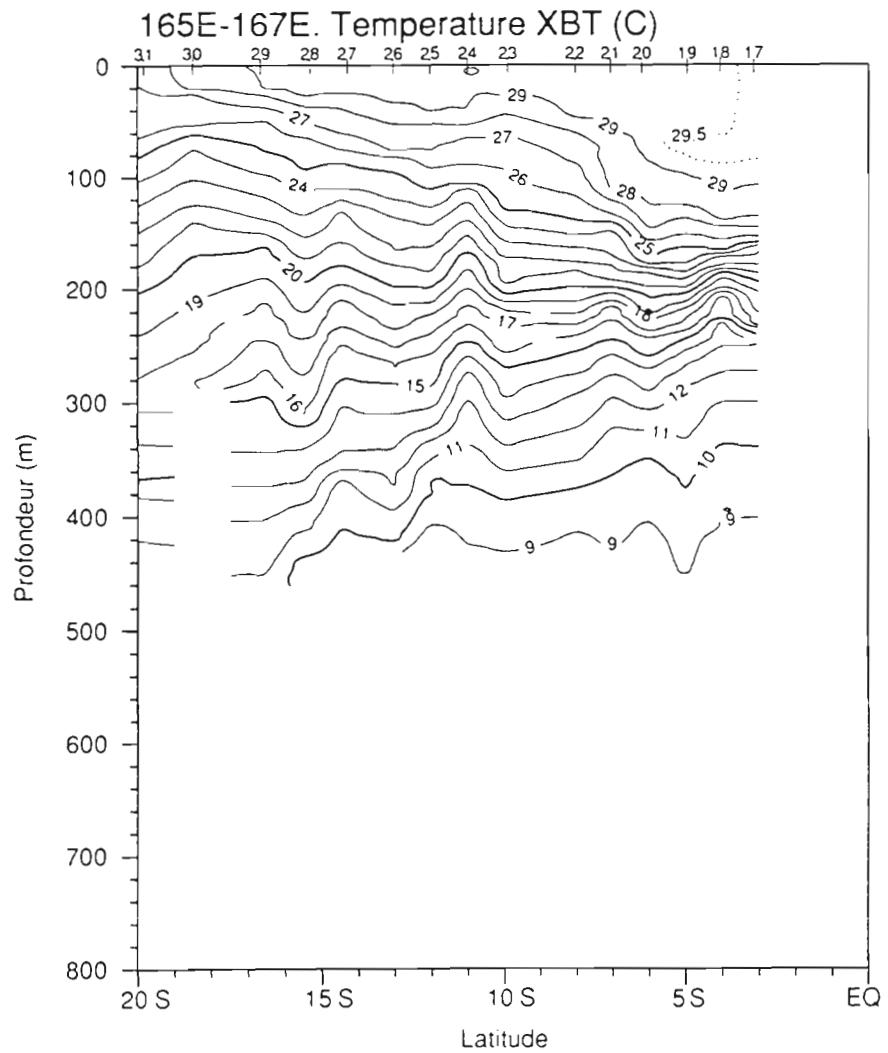

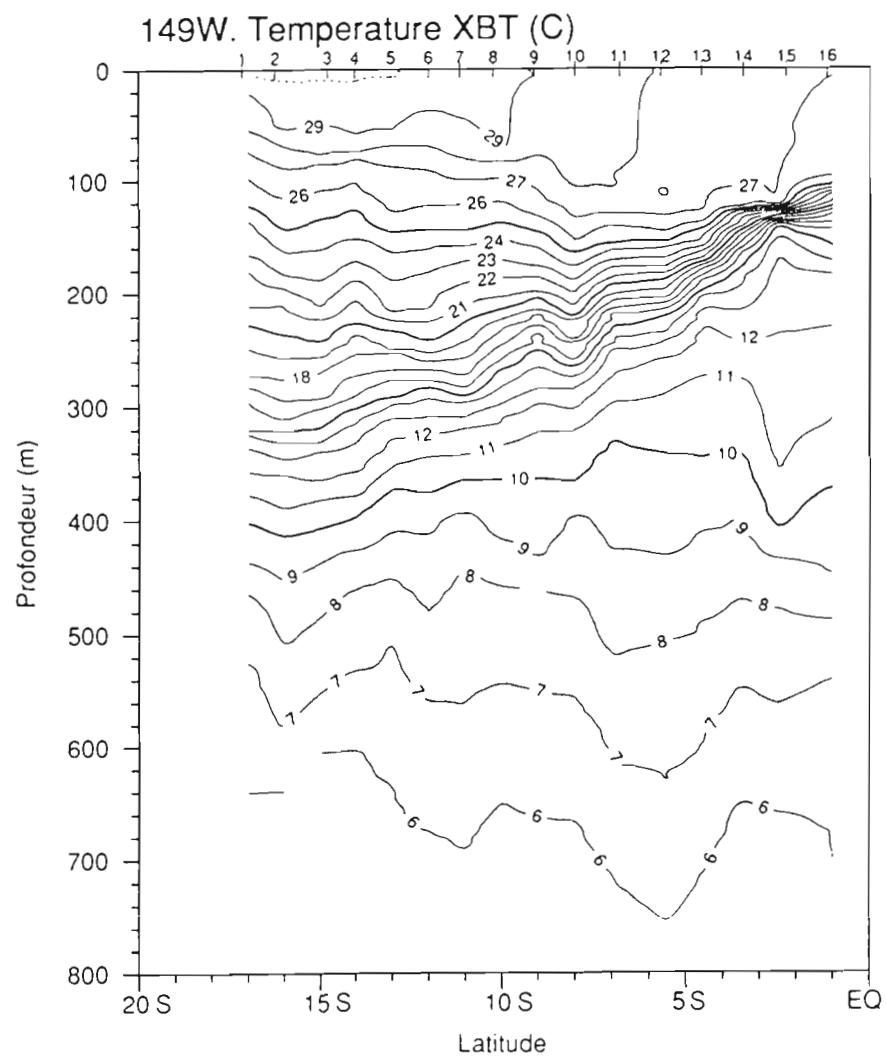

Comparaison sur trois jours du signal du capteur expérimental de pression partielle de gaz carbonique avec les mesures par analyseur à infra-rouge pendant ALIZE2.

Coupes des données XBT.

Les coupes verticales de température obtenues pour les deux radiales méridiennes à 149°W et 165°E sont présentées à partir des données des XBT, après interpolation des valeurs sur une grille de 0.5°C x 5m. Les profils ont été faits aux positions suivantes:

| Position | date | sonde | Position | date | sonde |
|-----------------|-------------|-------|----------------|-------------|-------|
| 17°11'S 149°30W | 08/02 03:23 | T7 | 16°15S 149°19W | 08/02 08:11 | T7 |

ANNEXE 2

Coupes verticales de courant.

Les résultats des observations à l'aide du profileur à effet Doppler acoustique sont présentés sous forme de coupes verticales de vitesse zonale (U) et méridienne (V) où les profils sont moyennés tous les 0.25 degré, puis interpolés sur une grille de maille 0.25 degré par 10 m. Les isolignes sont tracées tous les 10 cm/s, et les valeurs négatives (U vers l'ouest, V vers le sud) sont ombrées. Les coupes sont tracées pour chacun des segments de la campagne identifié dans le tableau suivant:

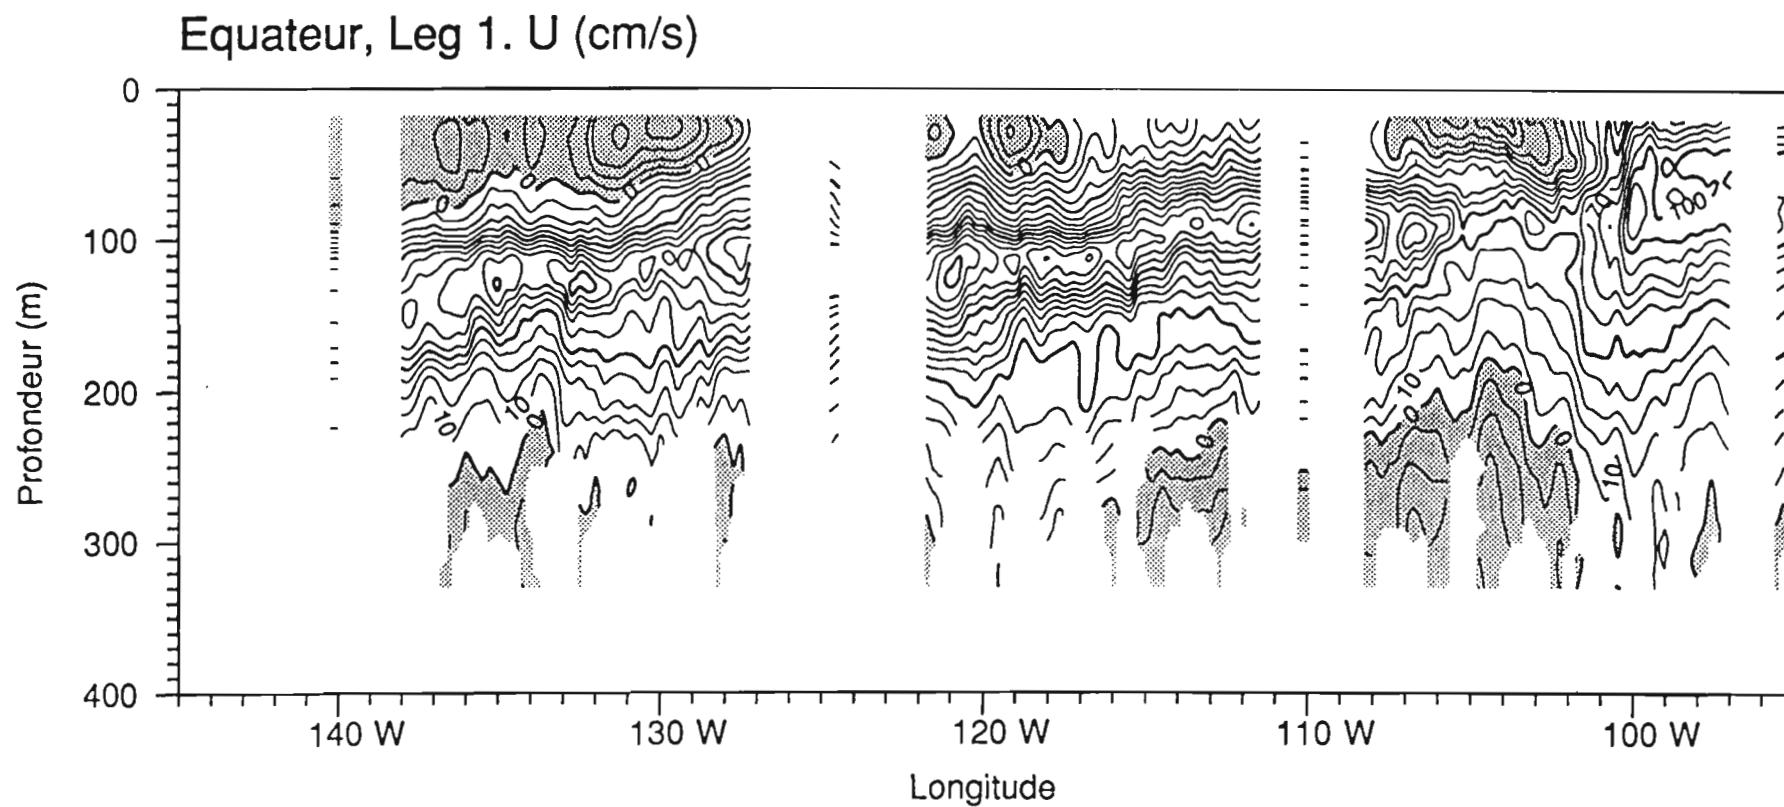

| Nom | Limites géographiques | | Dates | Notes |
|---------------|-----------------------|-------------------|----------------------------------|-------|
| Equateur Leg1 | 0.00 , 97.00 W | 0.00 , 108.34 W | 11-01-91 03:25 au 14-01-91 14:55 | |

(1) Les sections notées D1 et D2 sont les tronçons de route "diagonale" effectués pour rejoindre les extrémités des radiales méridiennes (D1 à l'Est de la radiale, D2 à l'Ouest).

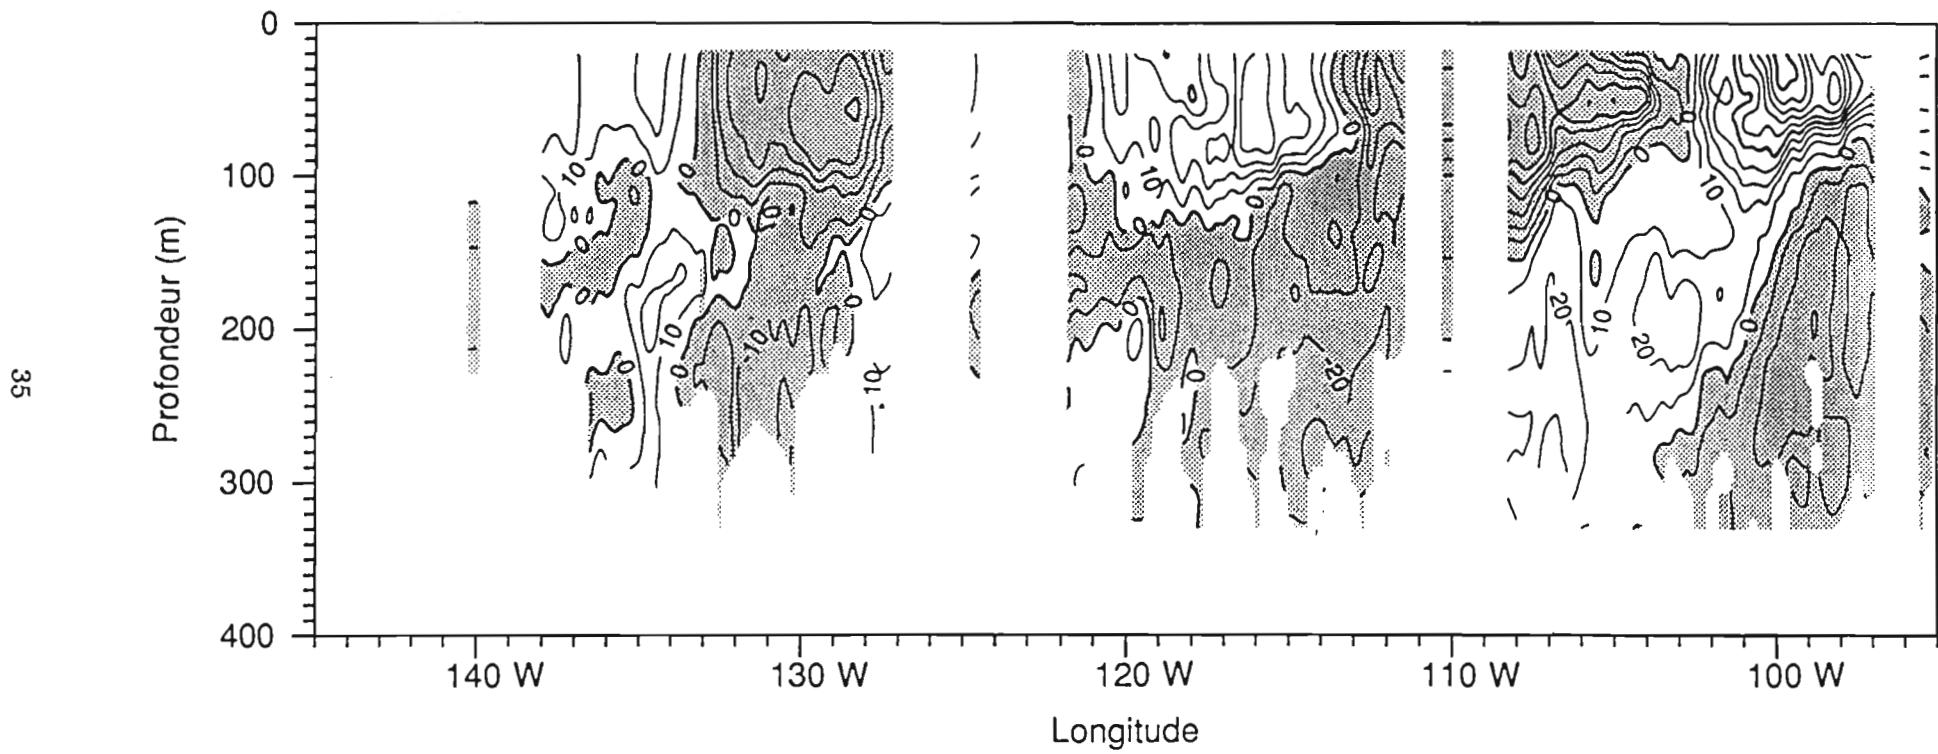

(2) Bien que diagonale, la section centrée sur 125W est considérée comme méridienne.

(3) Inclut aussi la radiale 2.5 S-2.5 N qui la prolonge naturellement.

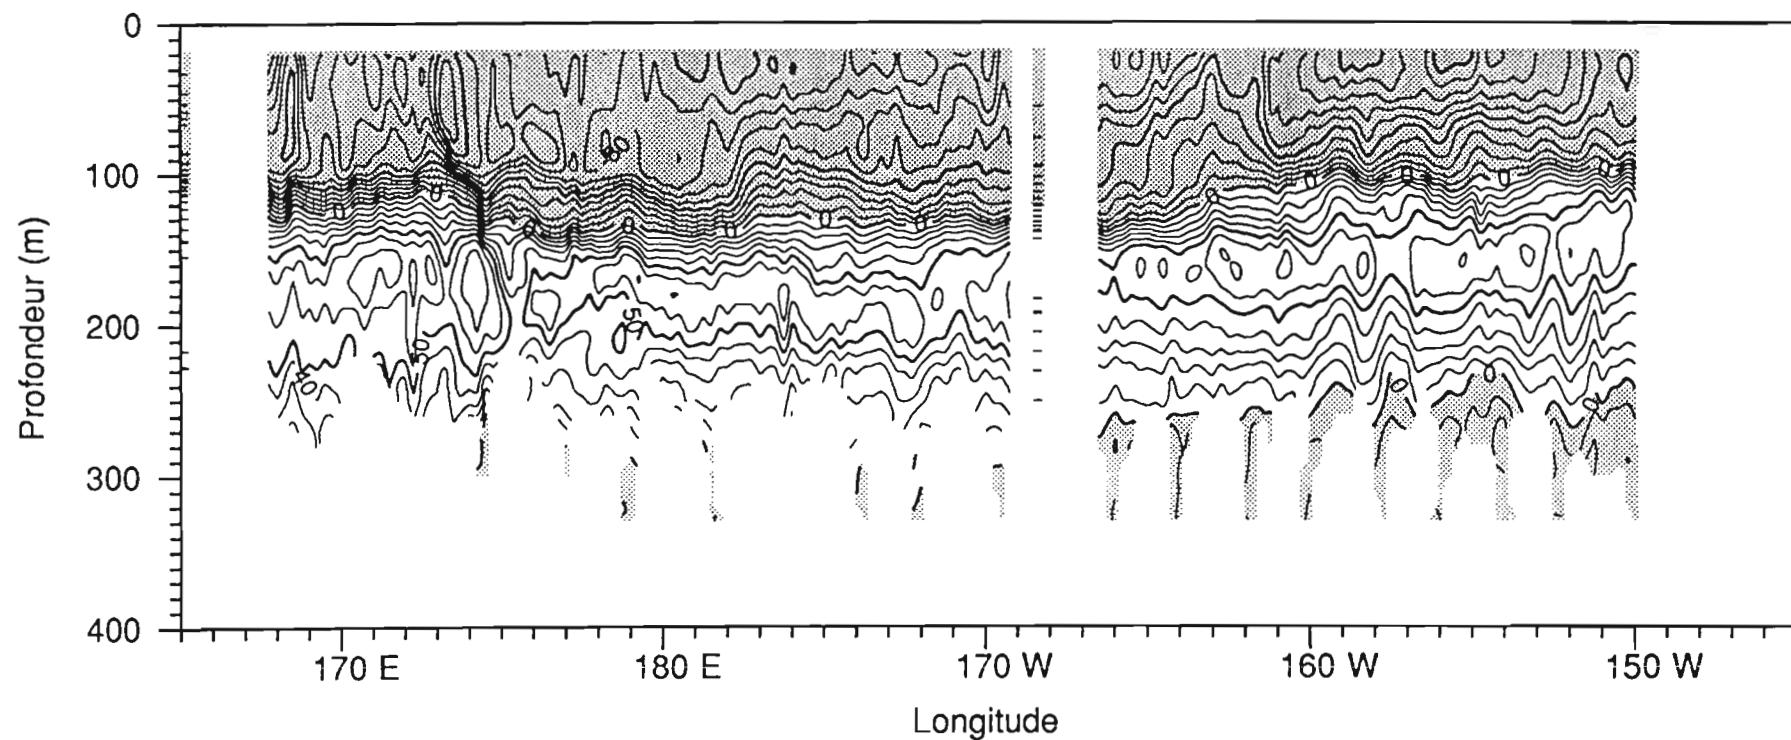

(4) Chaque section équatoriale est la réunion des tronçons de route séparant les sections méridiennes.

ANNEXE 3

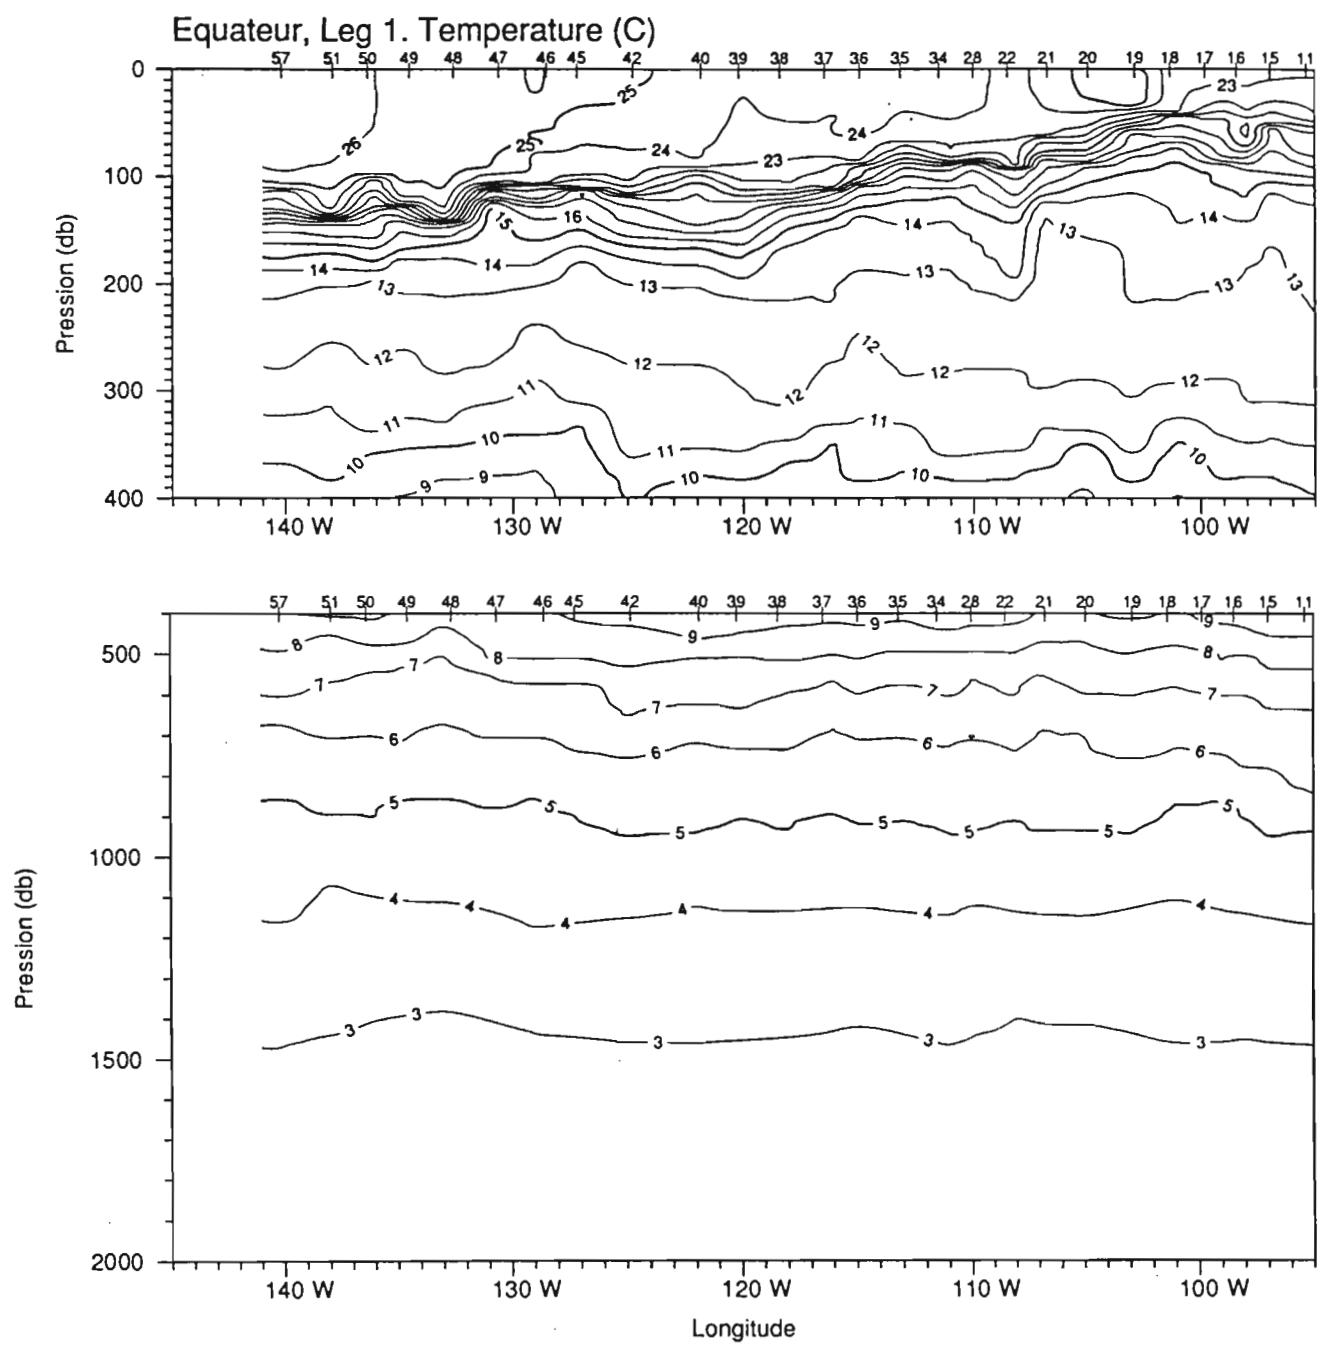

Coupes verticales des paramètres mesurés lors des stations

Des coupes verticales de distribution ont été tracées le long de l'équateur et de sections méridiennes pour les paramètres observés à l'aide de la bathysonde et ceux mesurés à partir des prélèvements effectués en station.

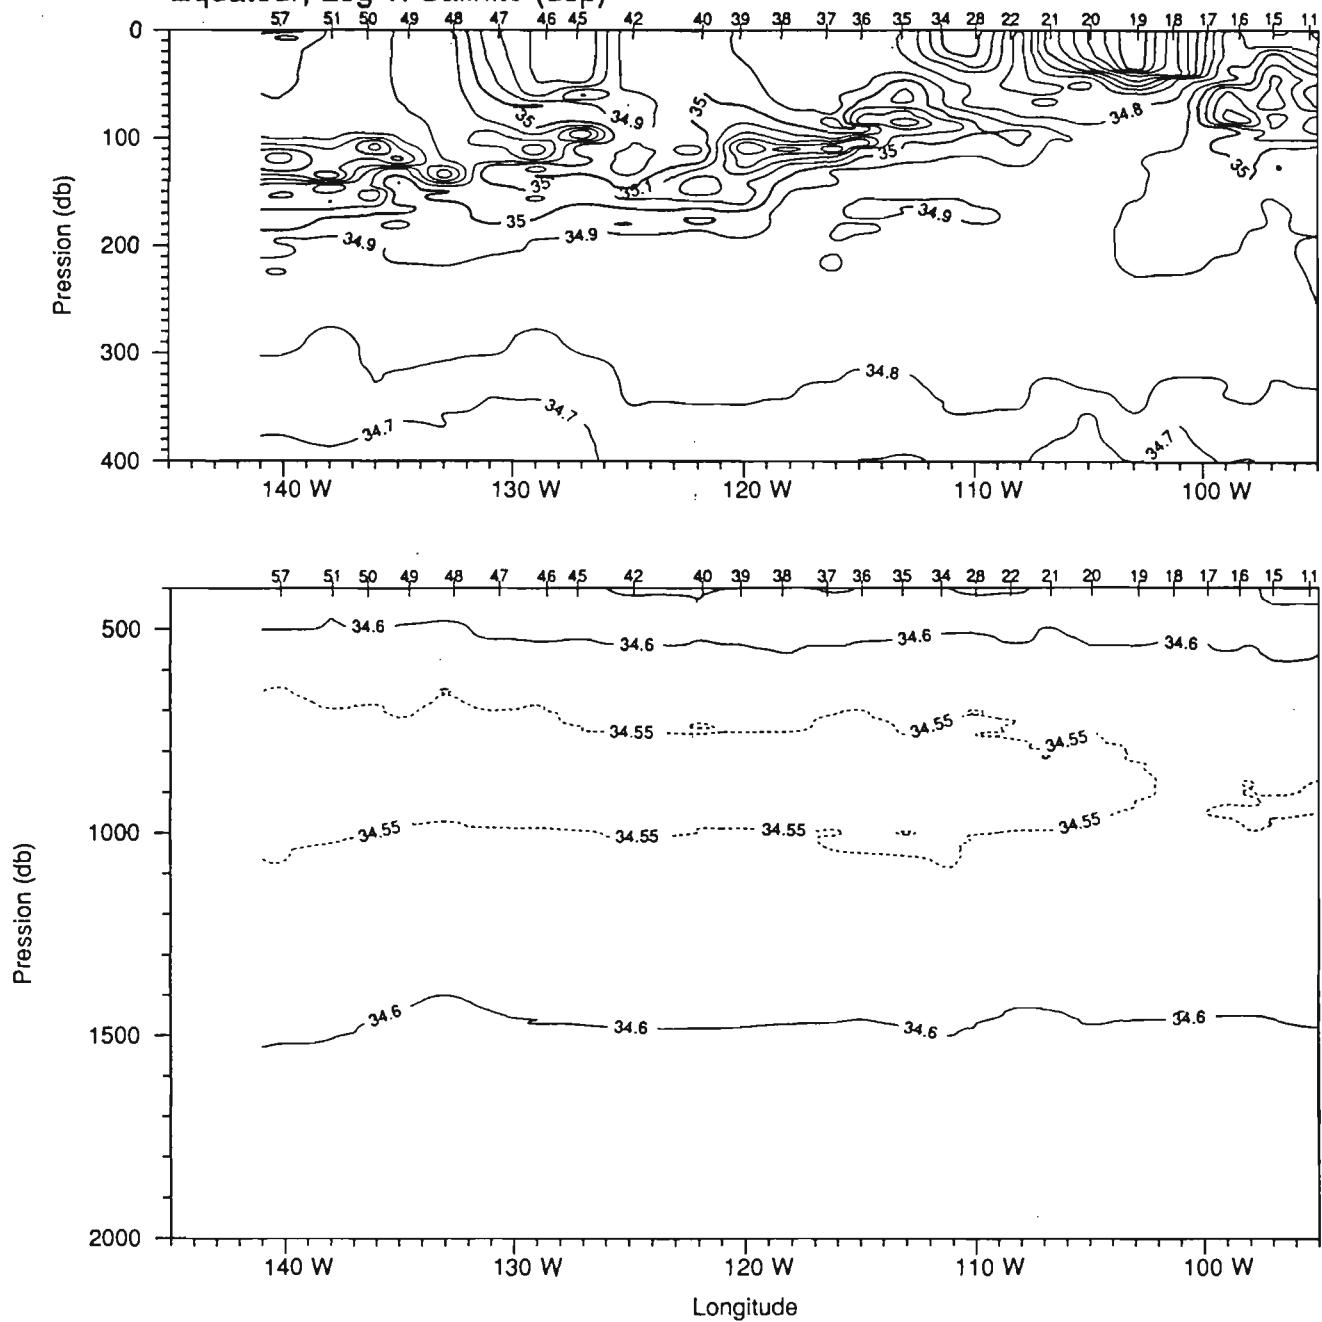

Ces coupes verticales concernent:

- les données bathysonde: T, S, O₂ et σ_{θ} ($\sigma_{\theta} =$ (masse volumique -1000) en kg/m³, la température potentielle de l'eau de mer a été utilisée pour calculer la masse volumique).
- les données de sels nutritifs: O₂ (bouteilles), PO₄, NO₂, NO₃ et SiO₄.
- les données de fréon F12 (leg1 seulement).
- les données de phytoplancton: chlorophylle a totale, micro-algues et cyanobactéries.
- les données de ¹³C (il s'agit de résultats partiels, les analyses étant encore en cours au moment de la rédaction de ce document).

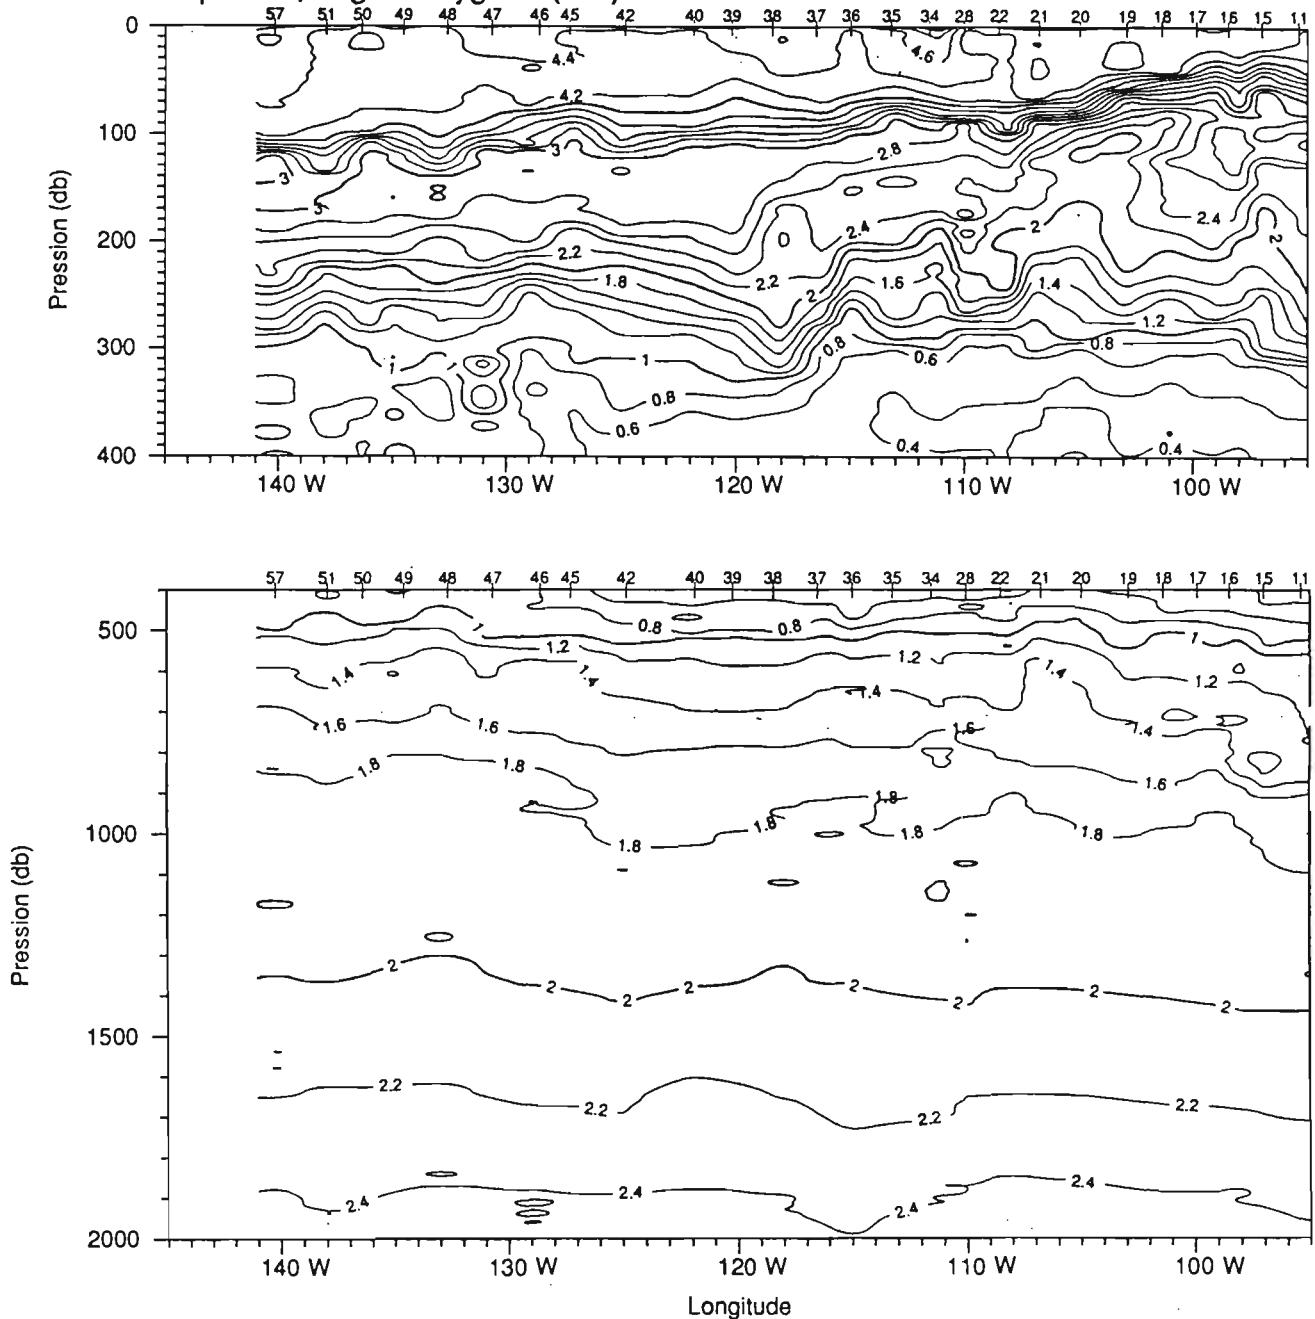

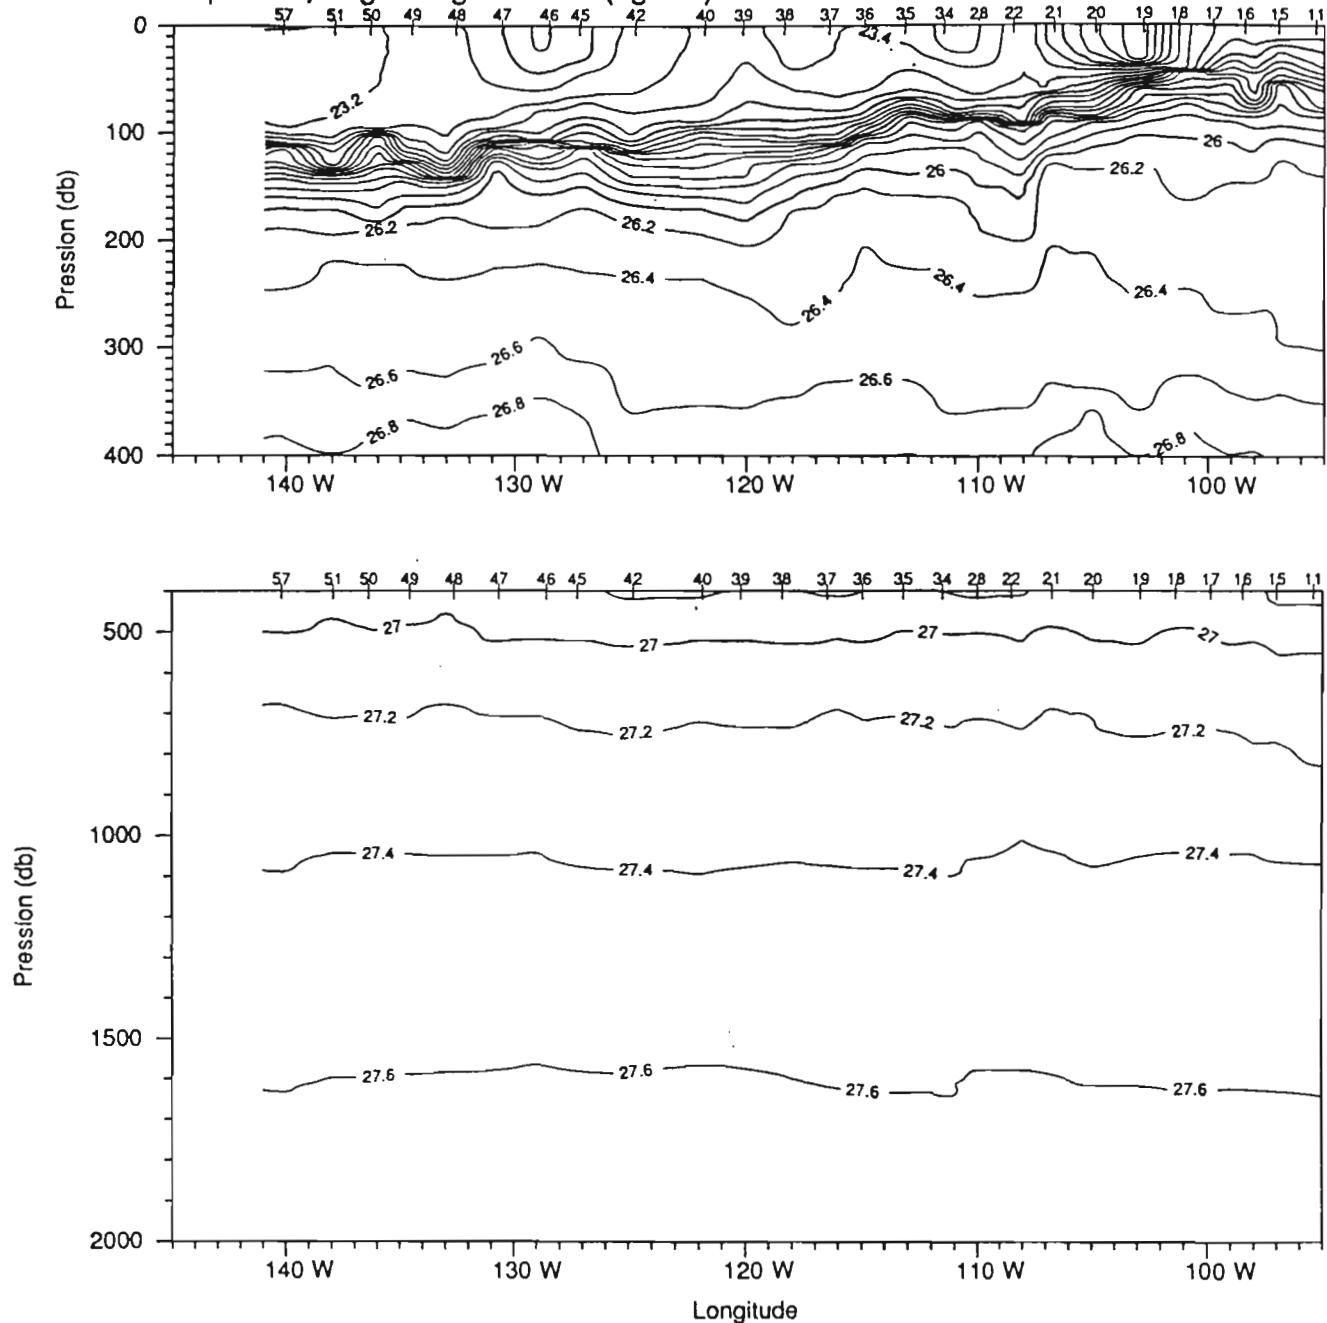

Equateur, Leg 1. Salinite (usp)

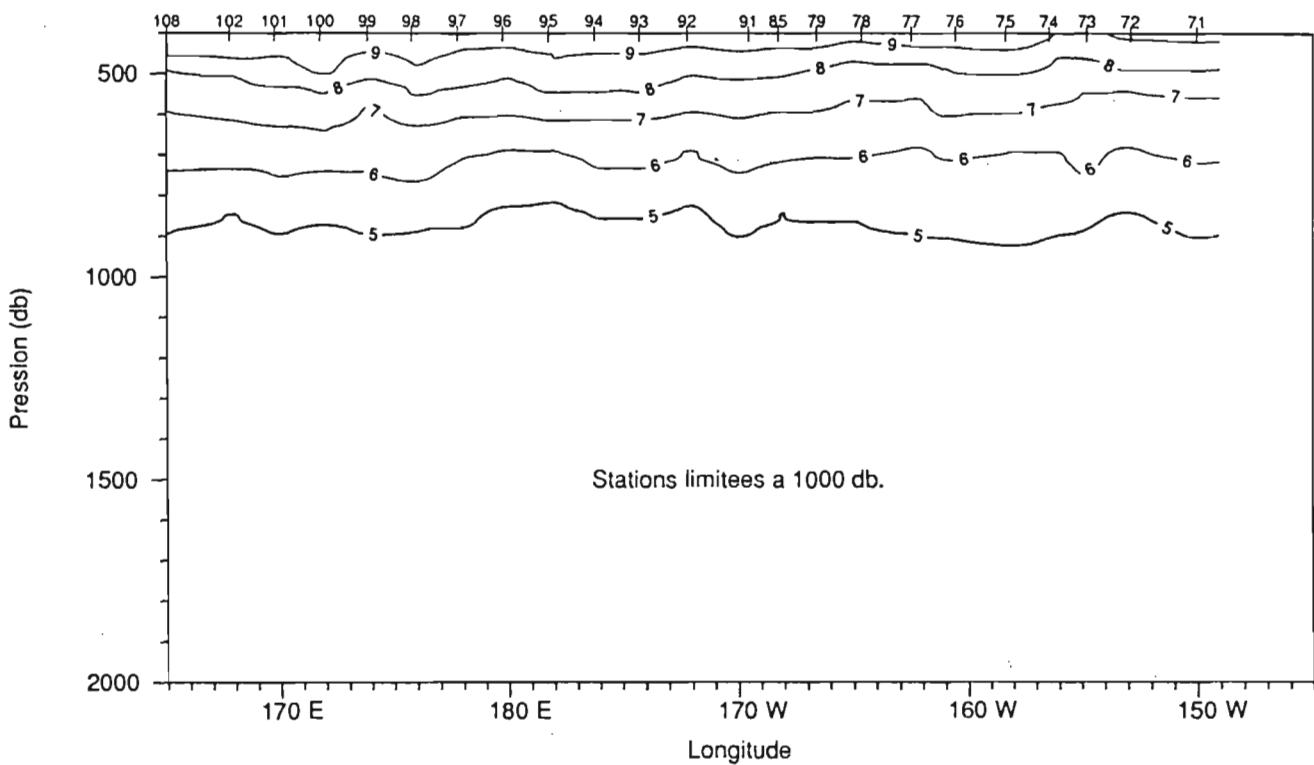

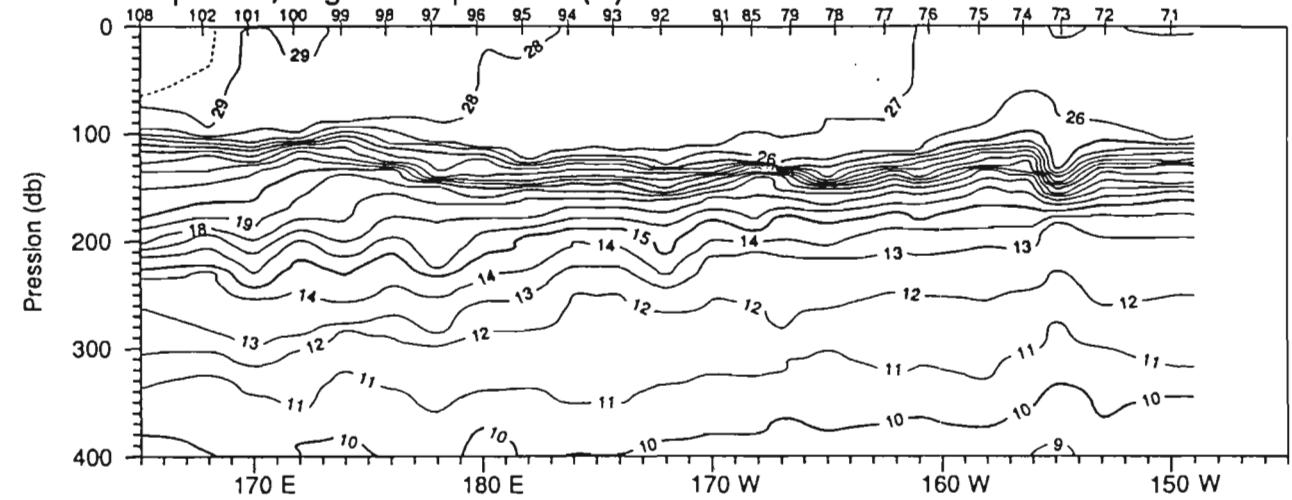

Equateur, Leg 1. Oxygene (ml/l)

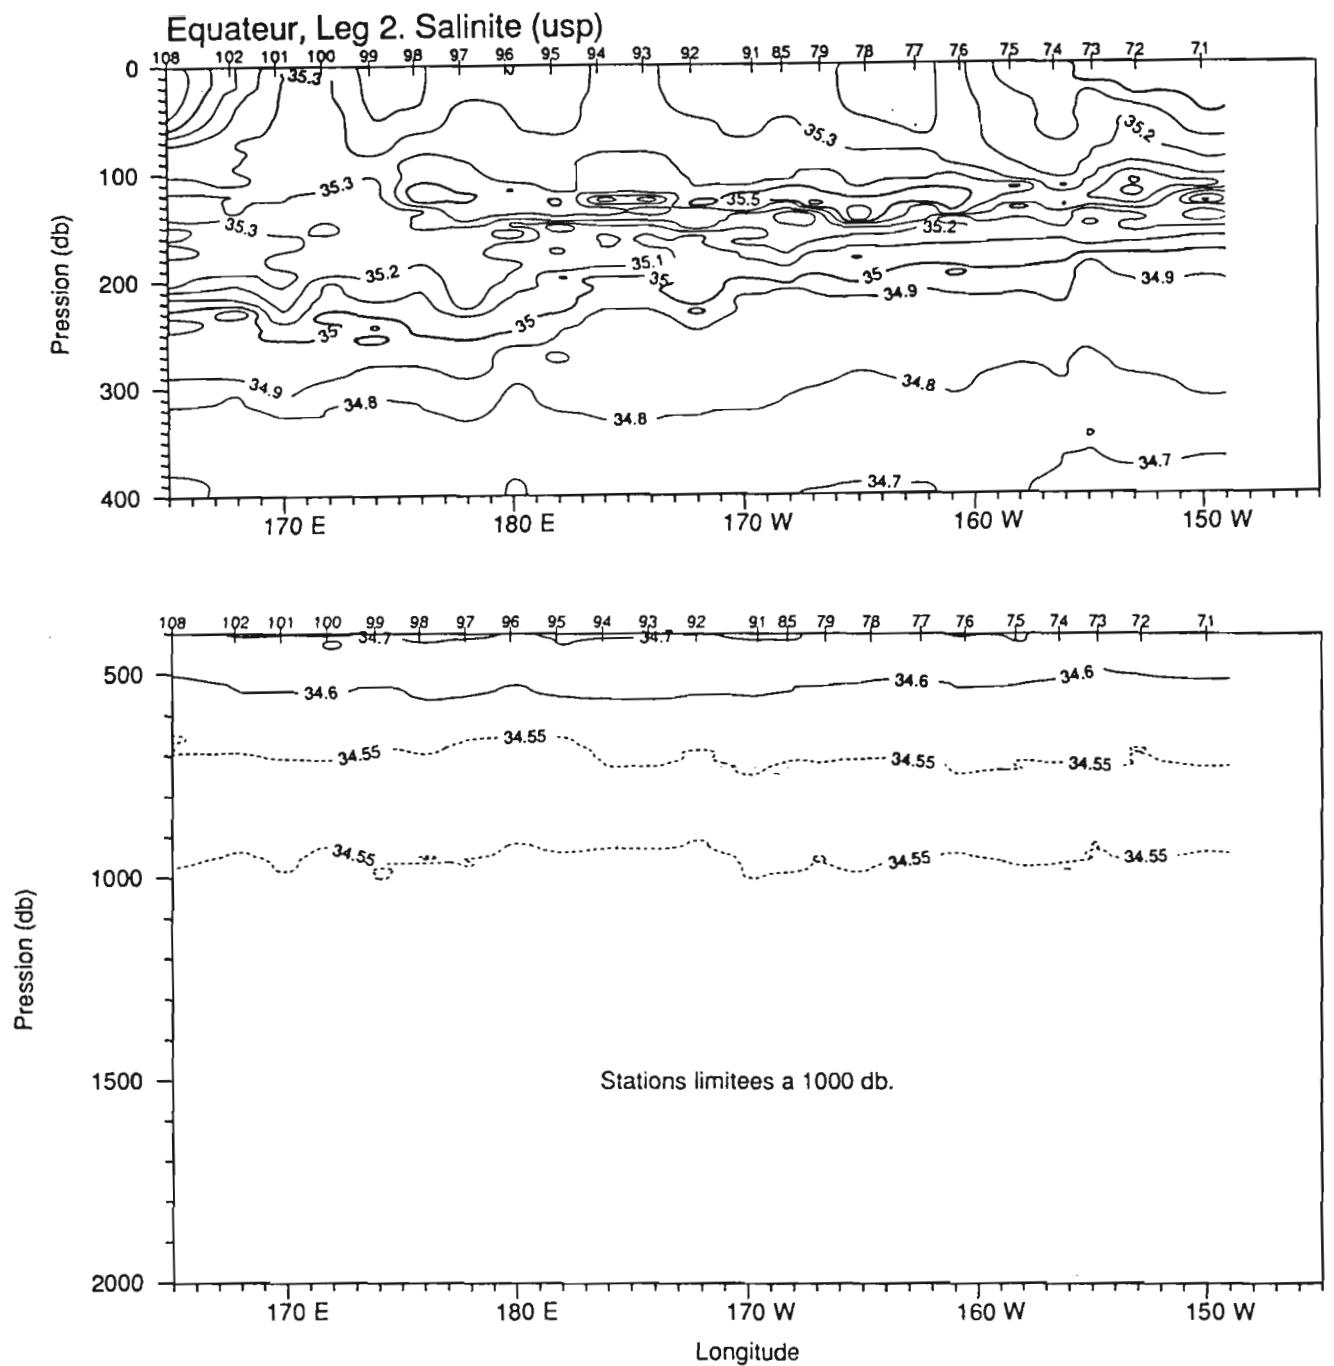

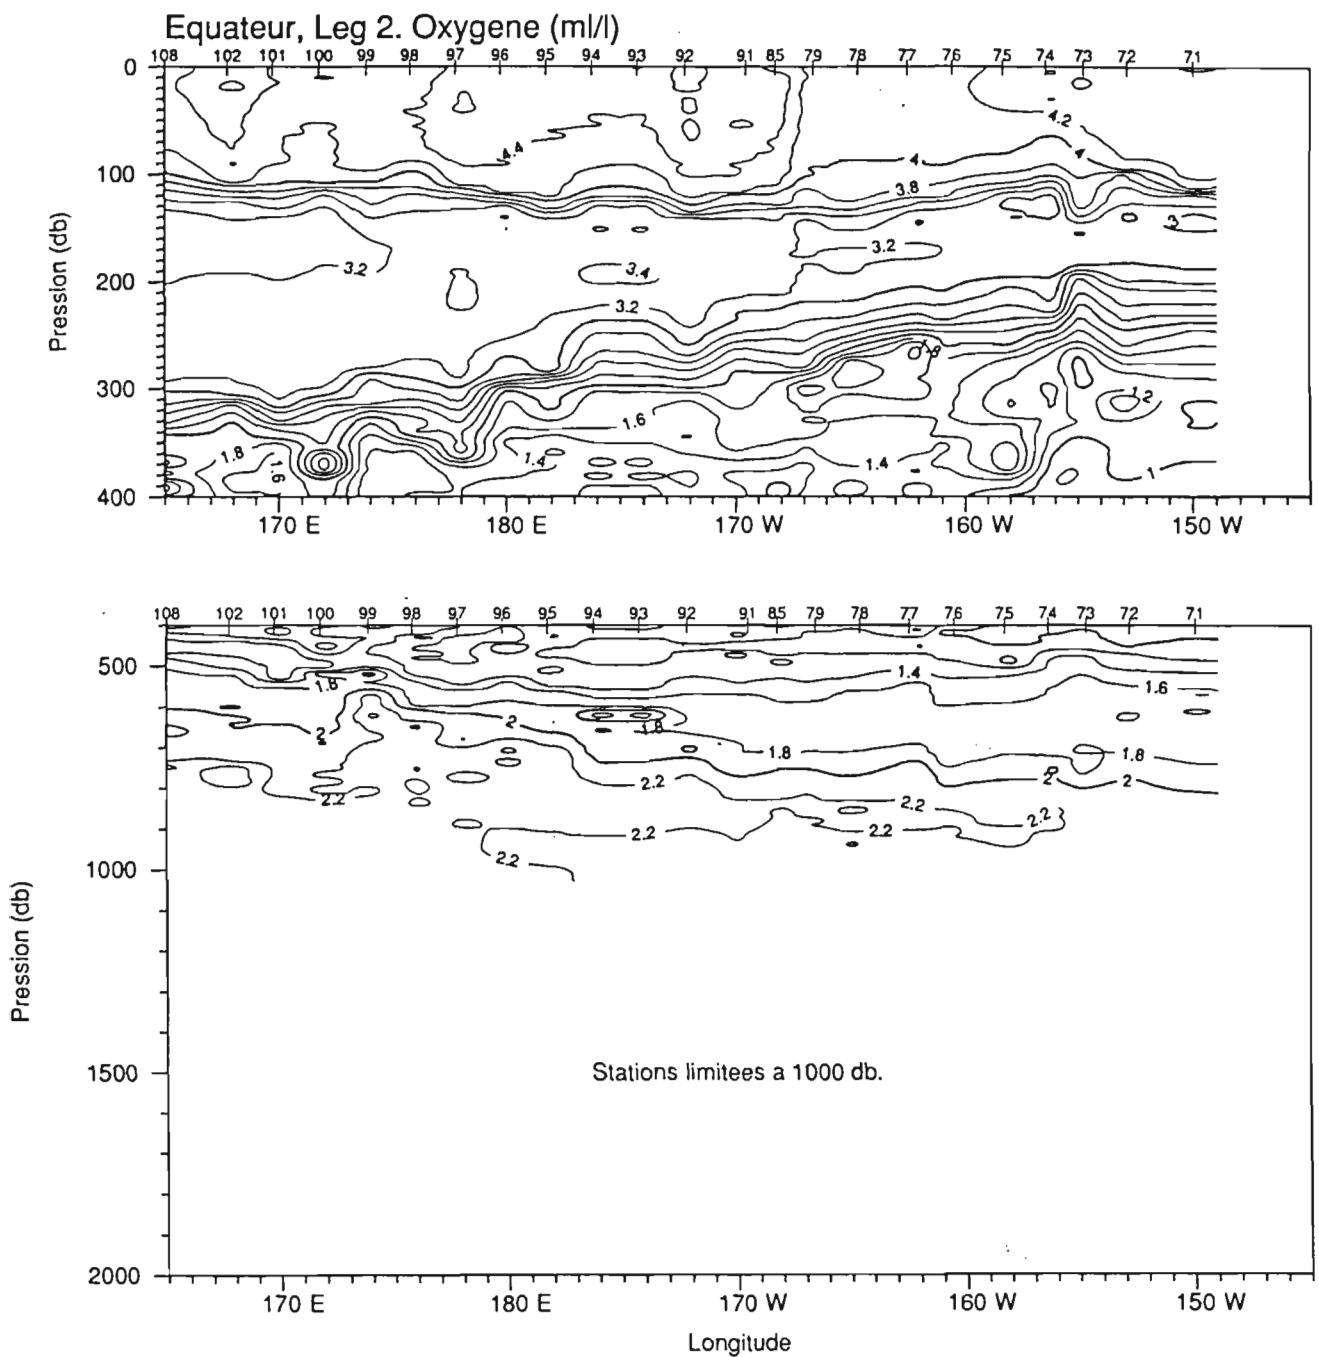

Equateur, Leg 1. Sigma theta (kg/m³)

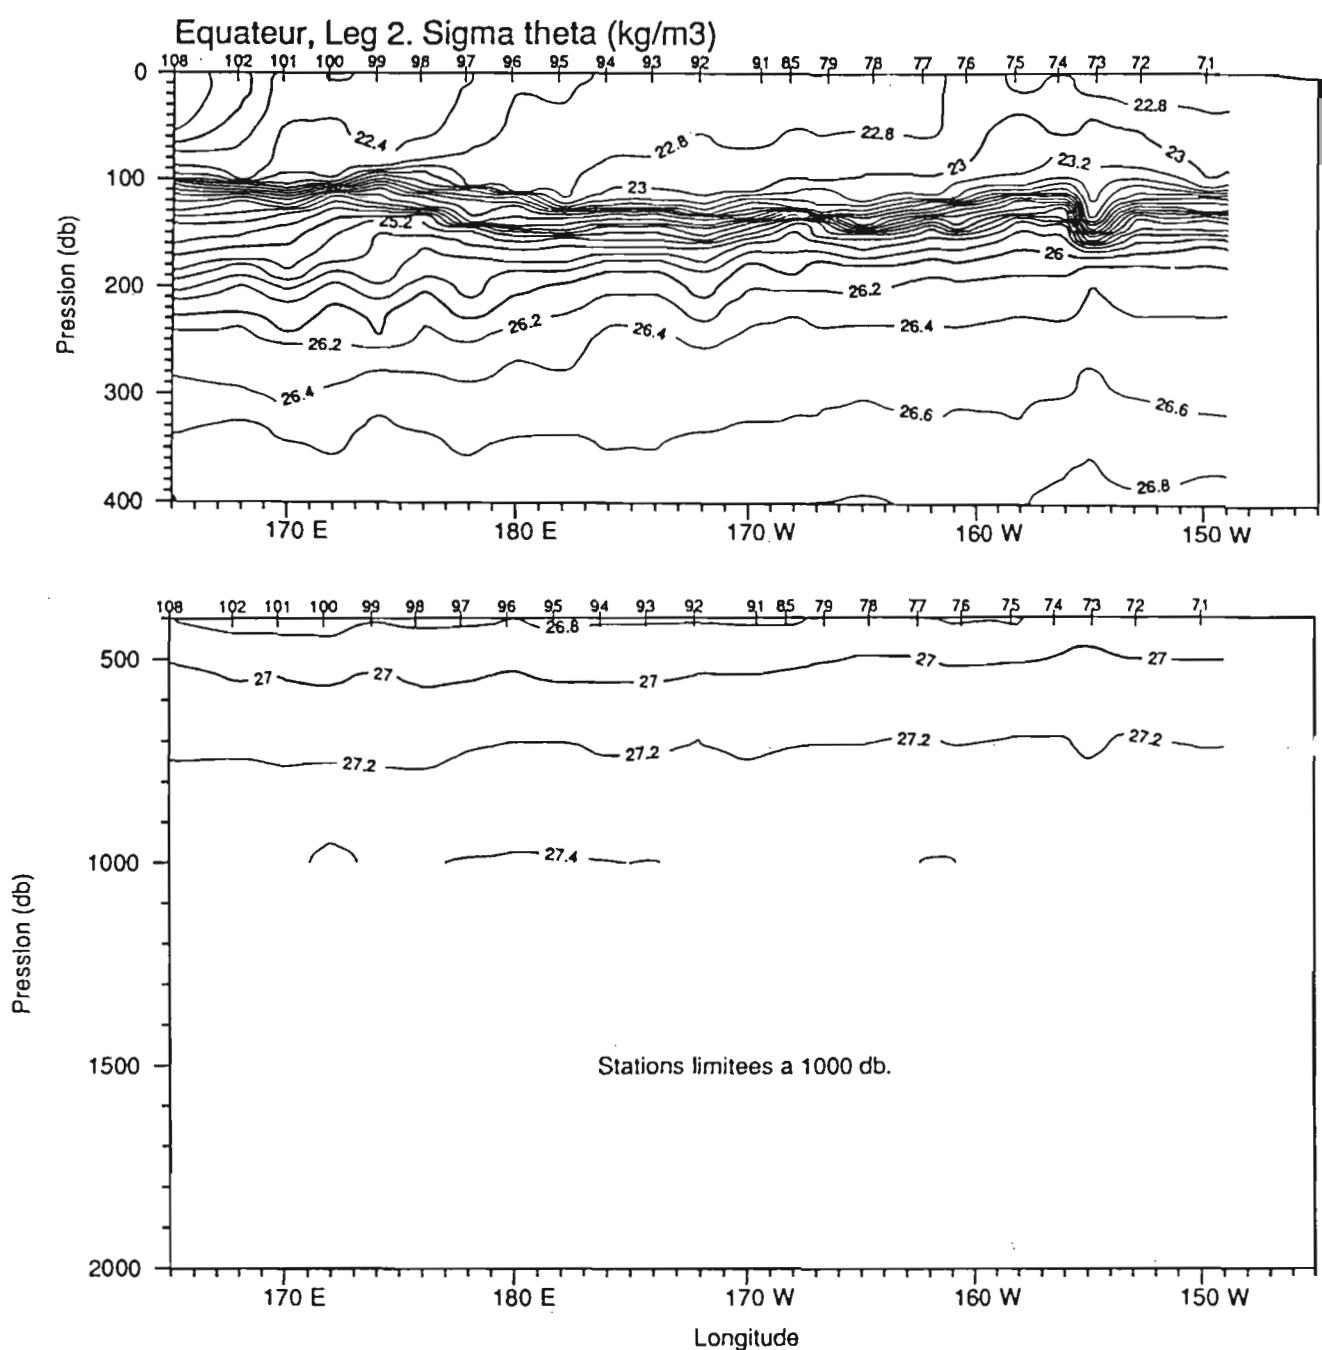

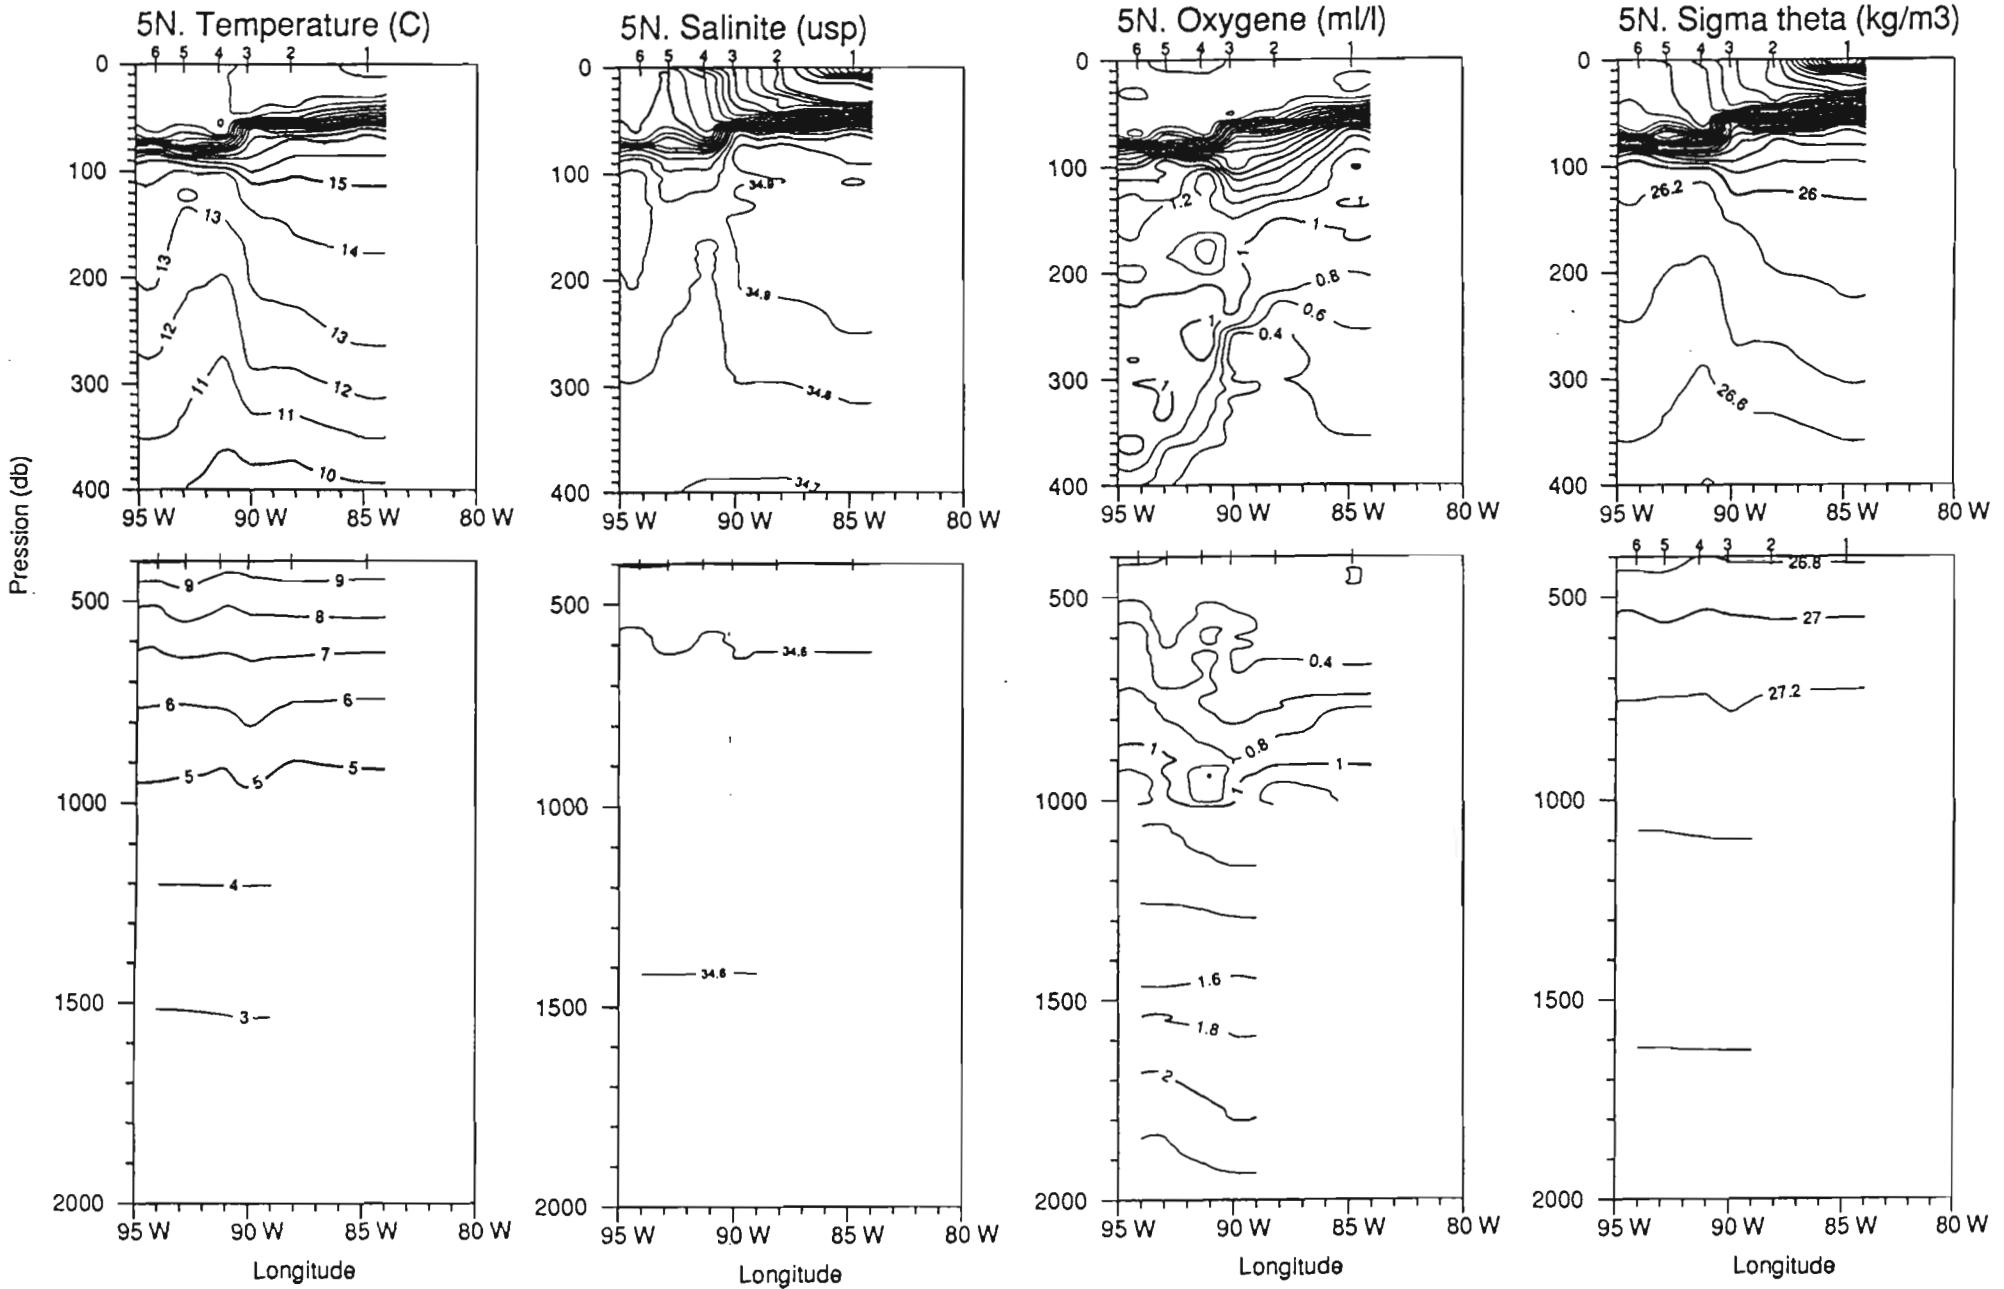

Equateur, Leg 2. Temperature (C)

86

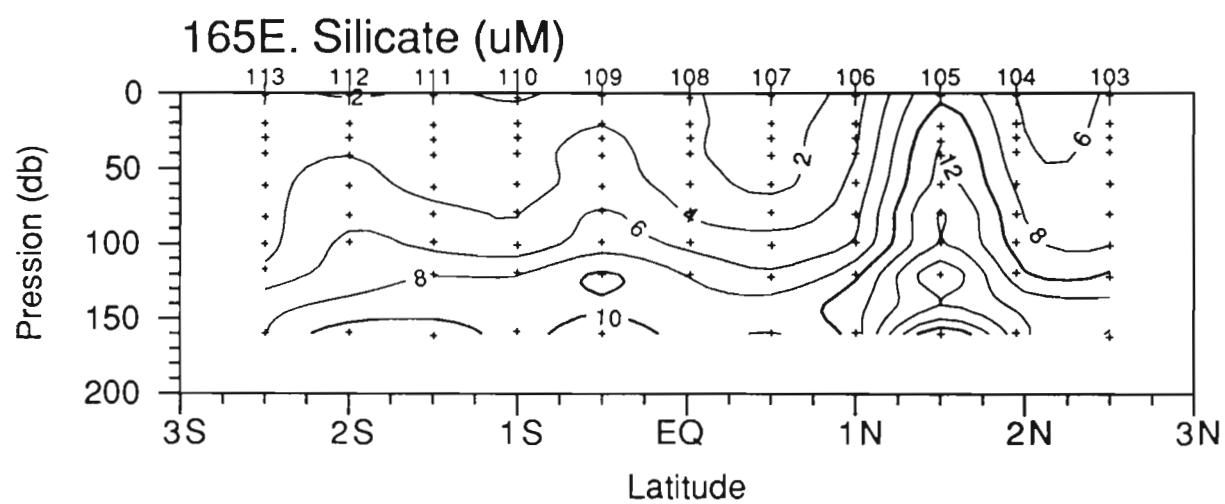

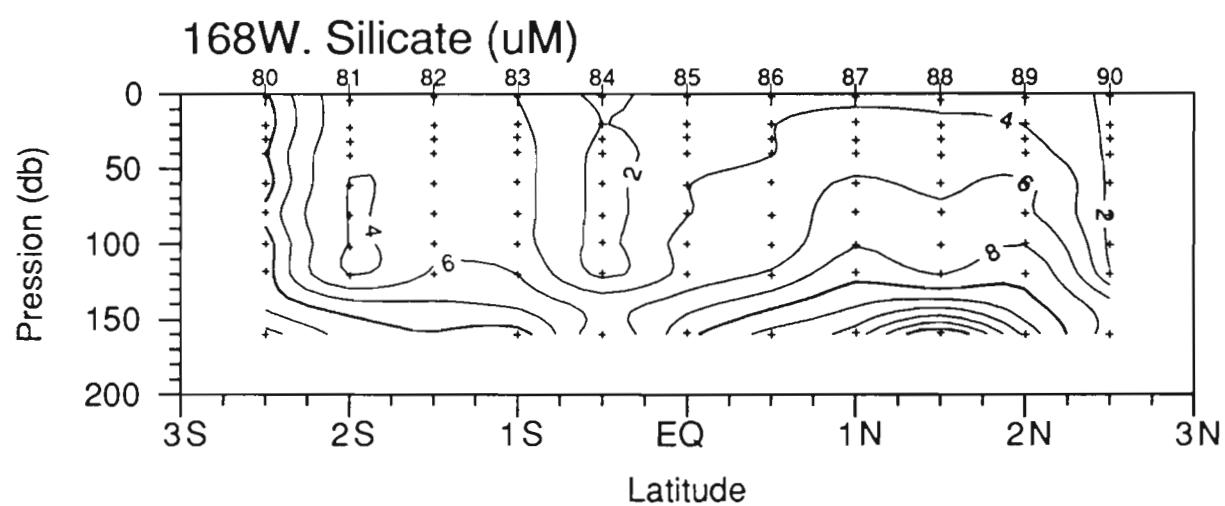

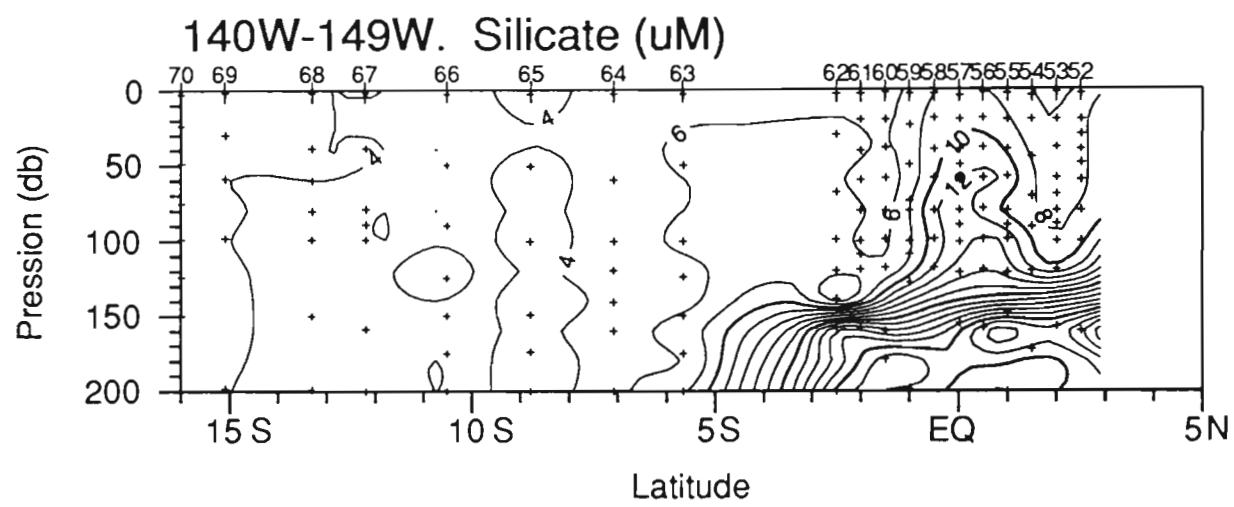

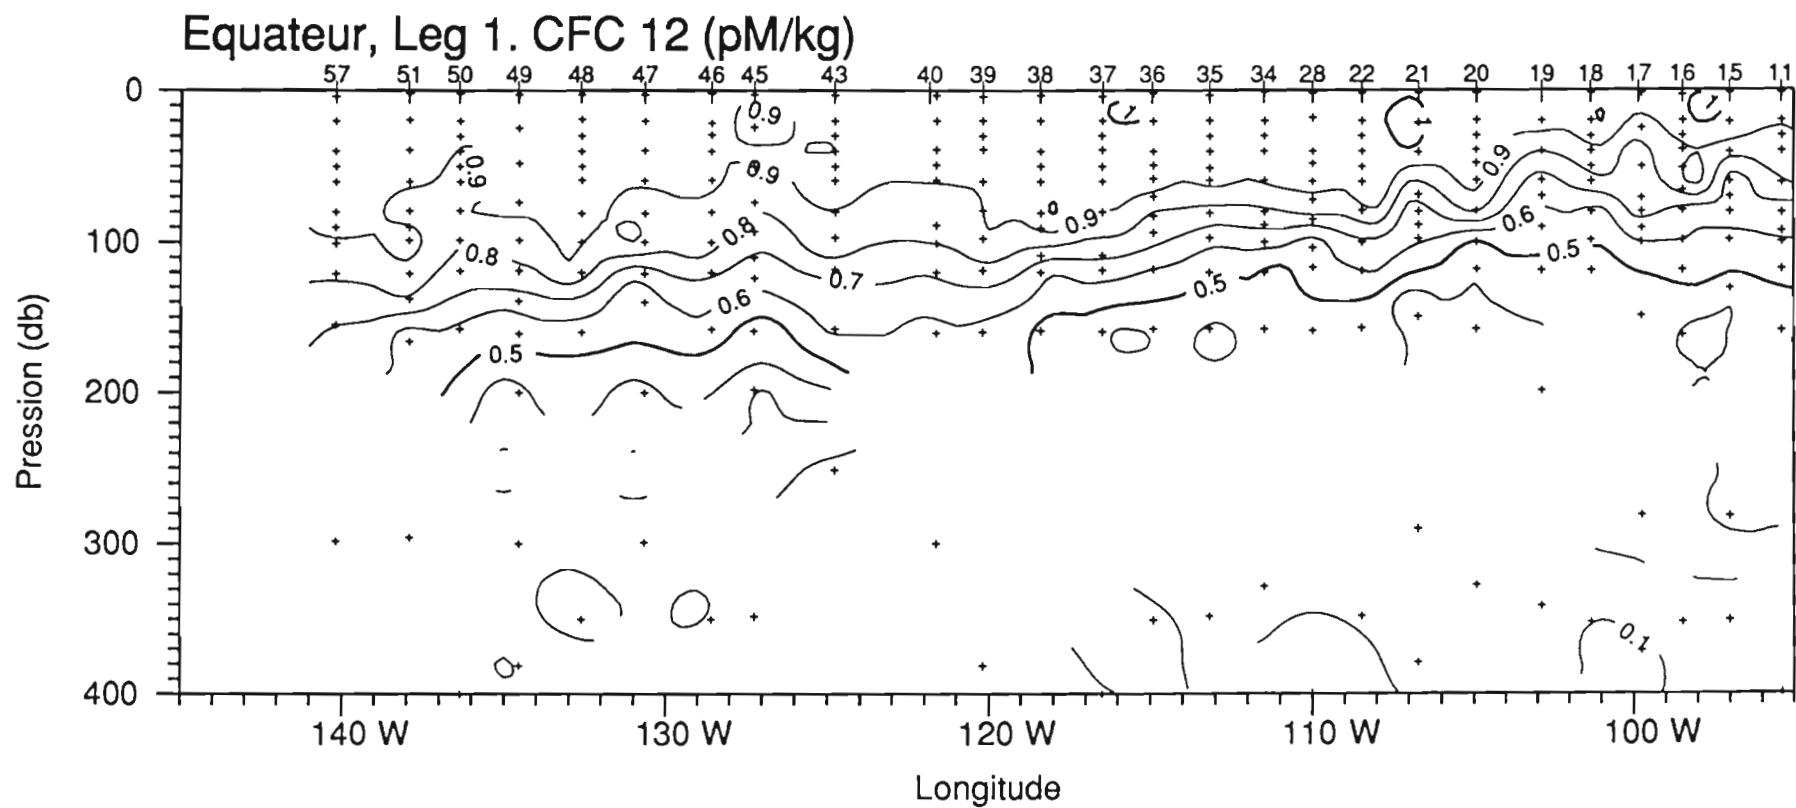

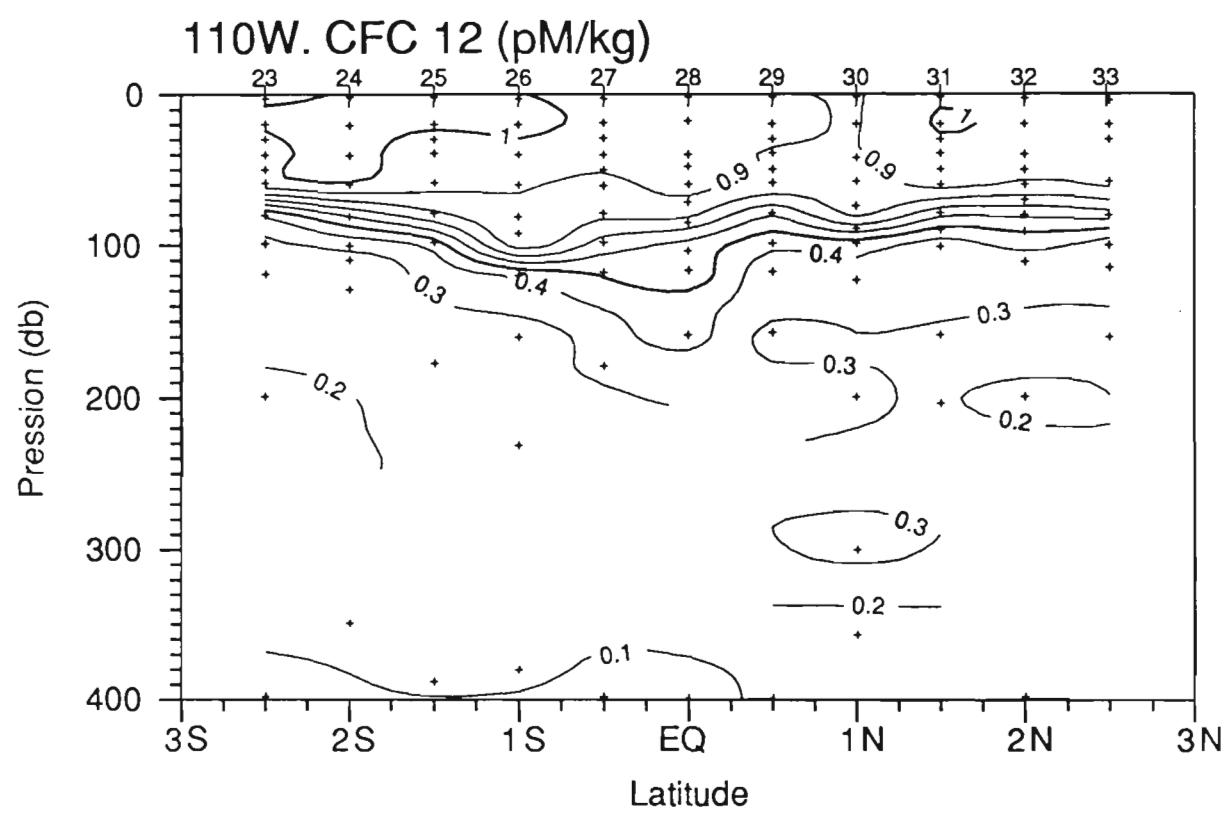

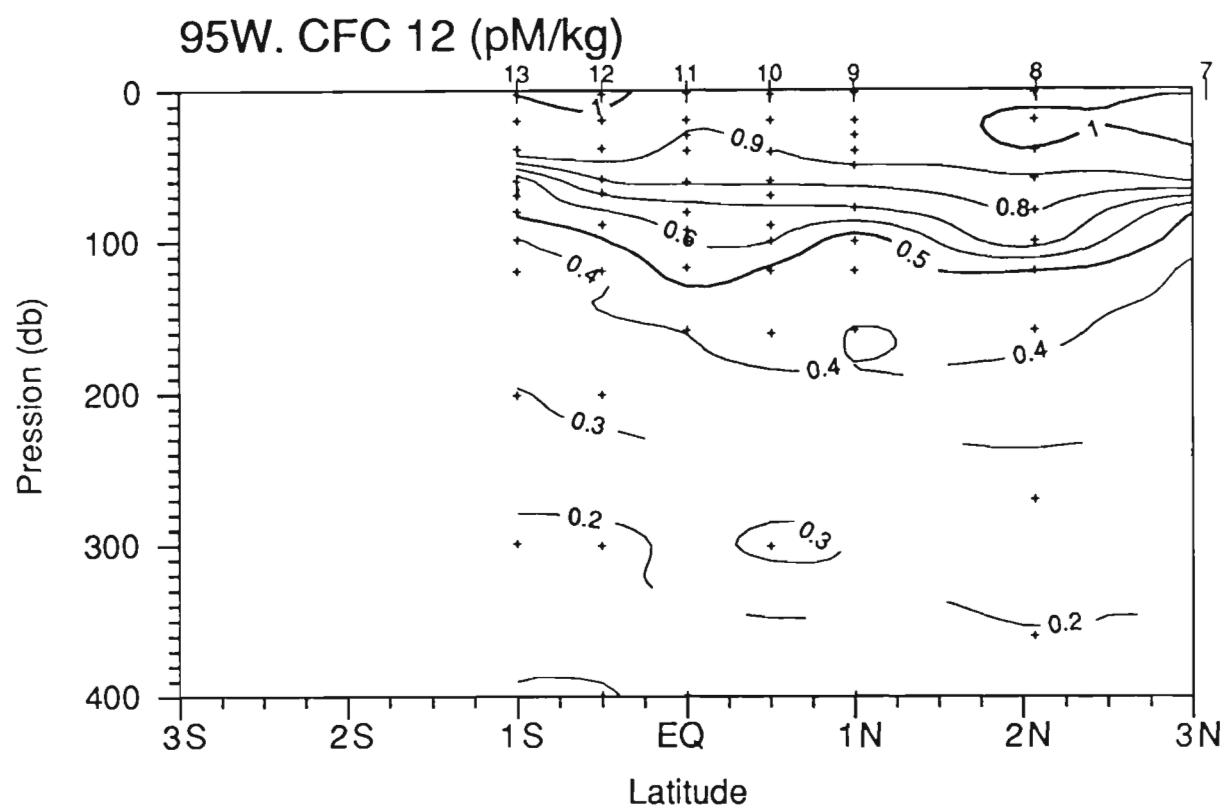

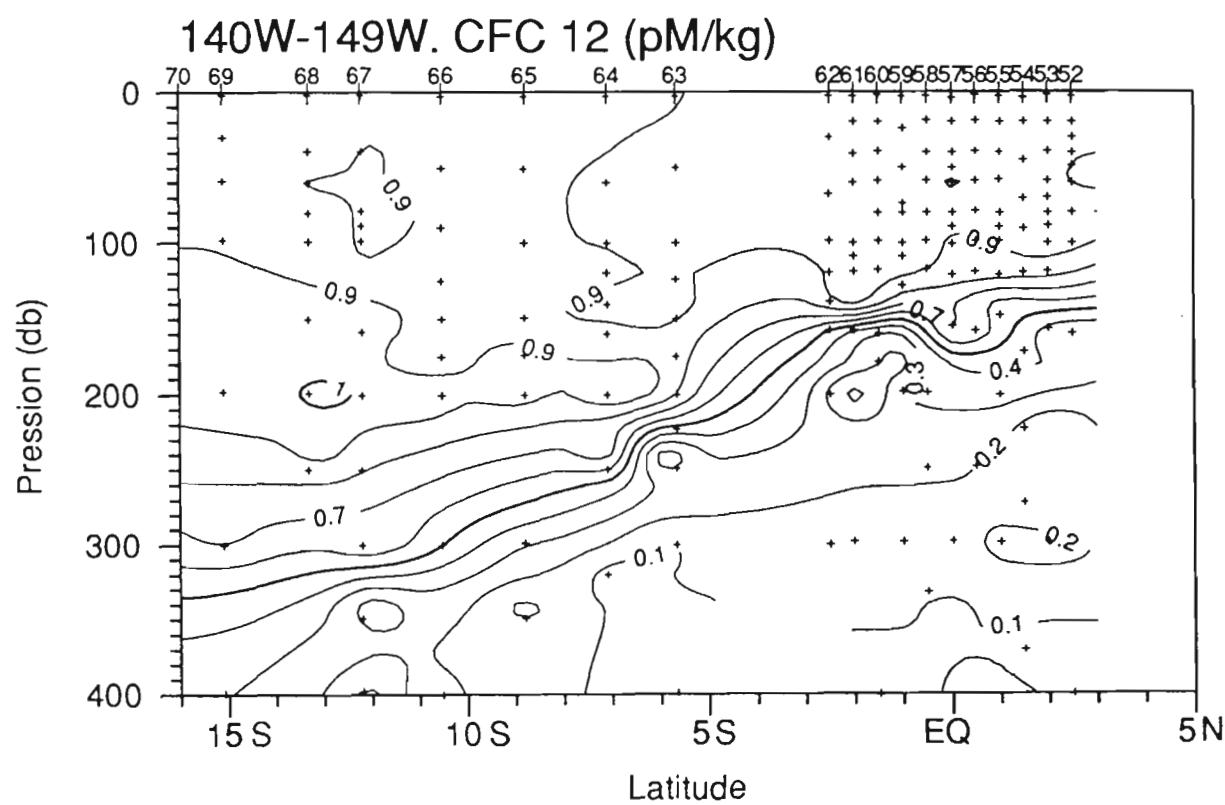

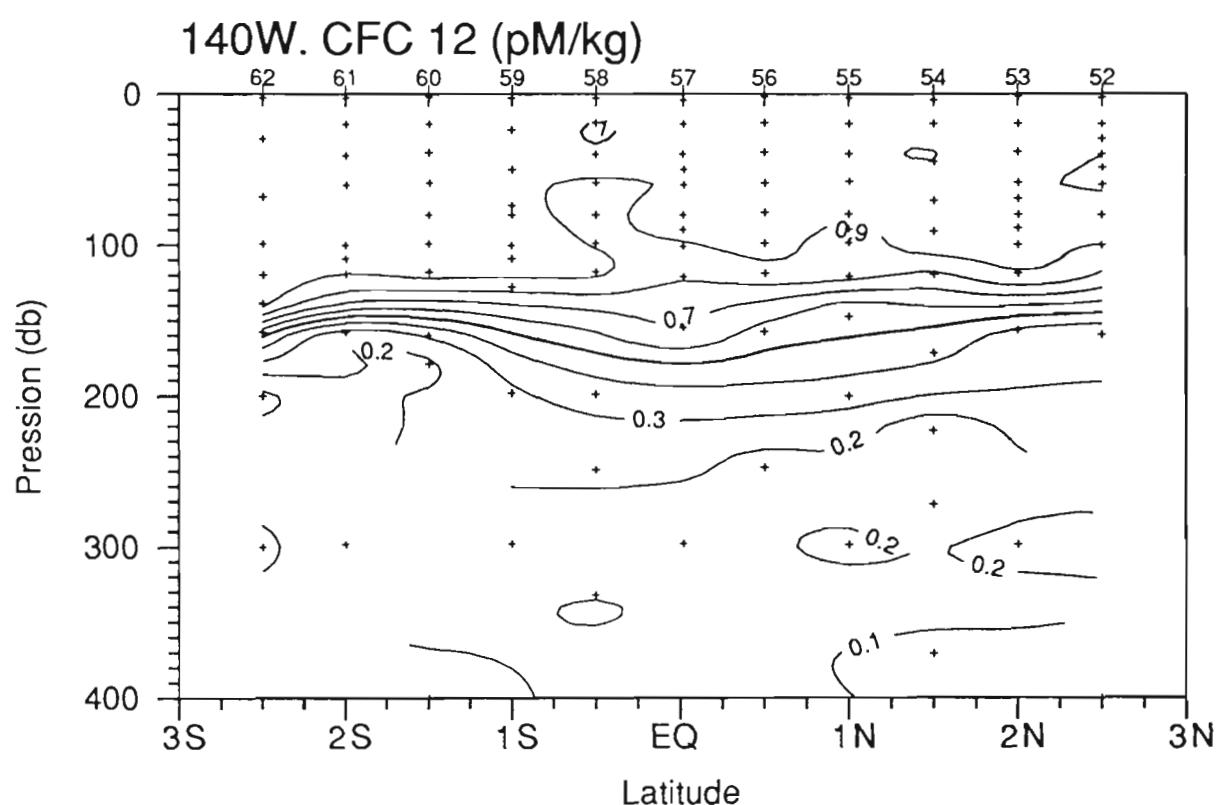

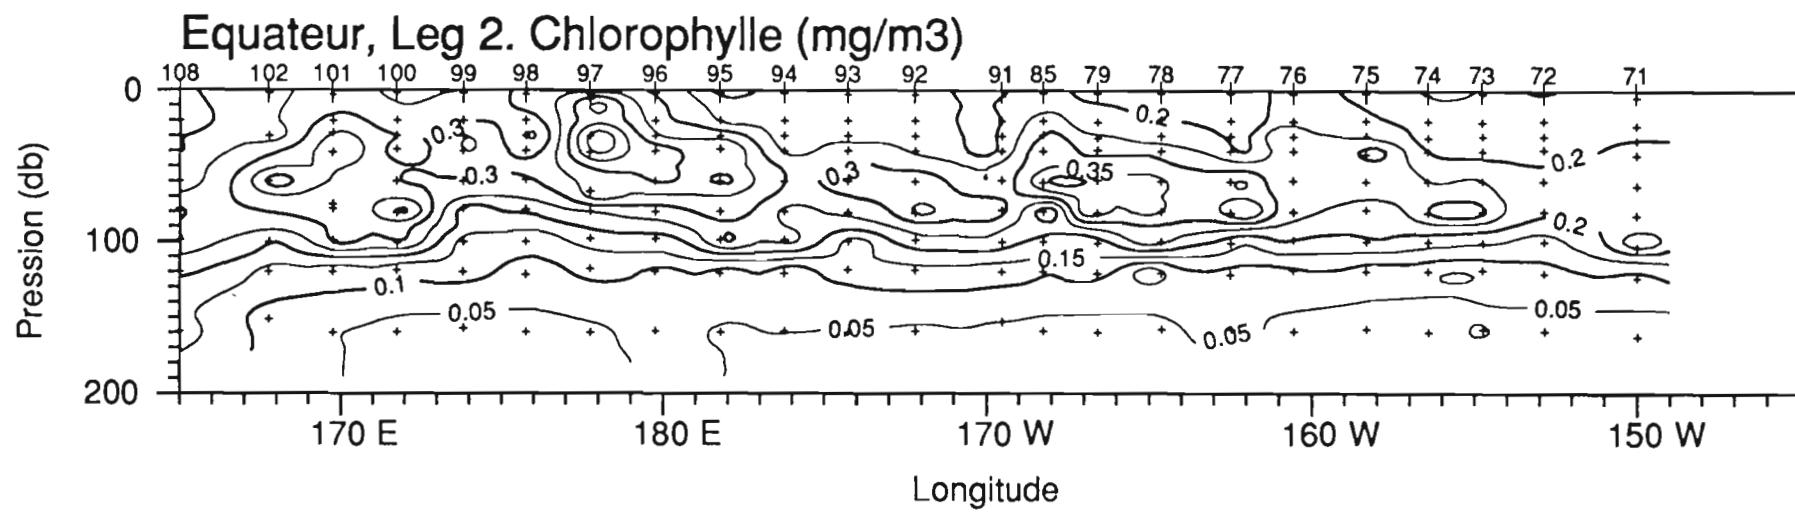

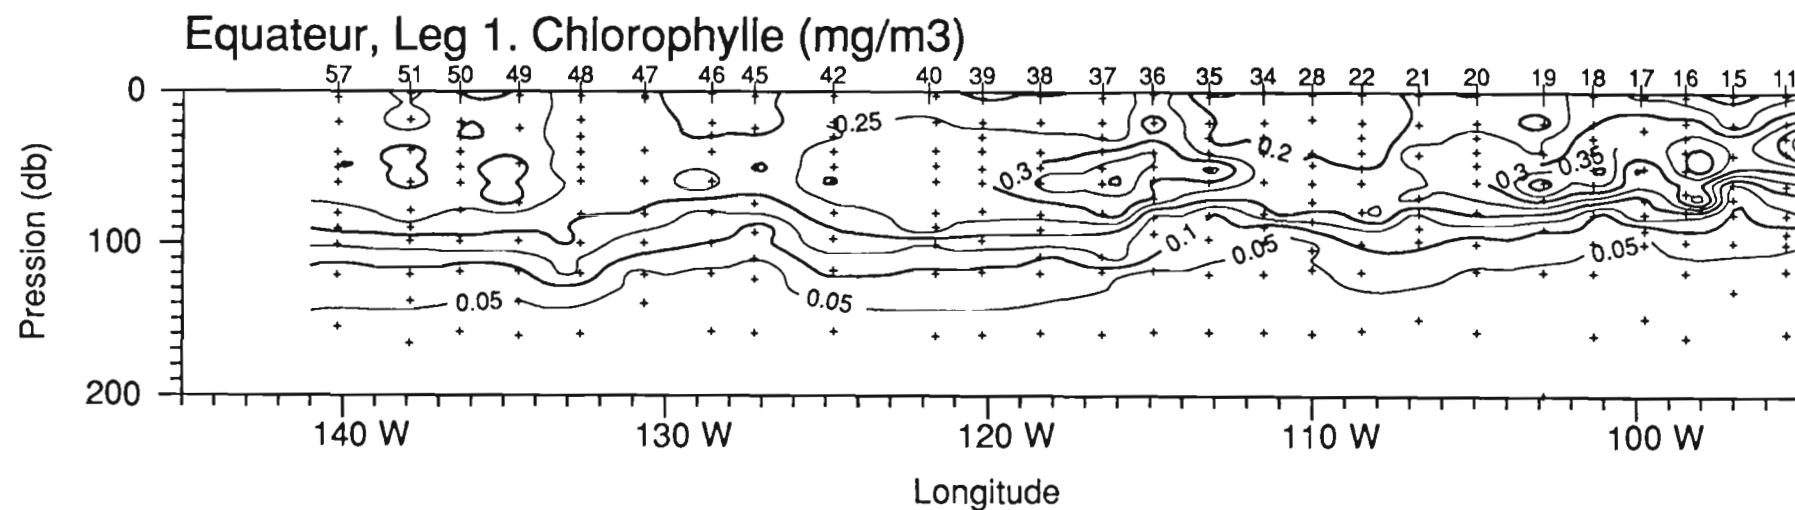

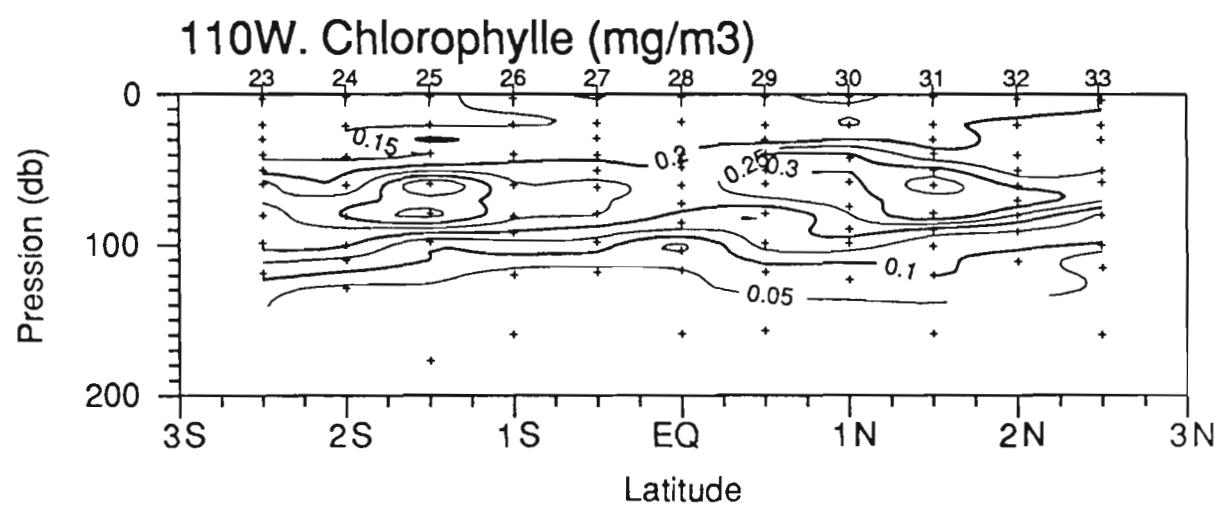

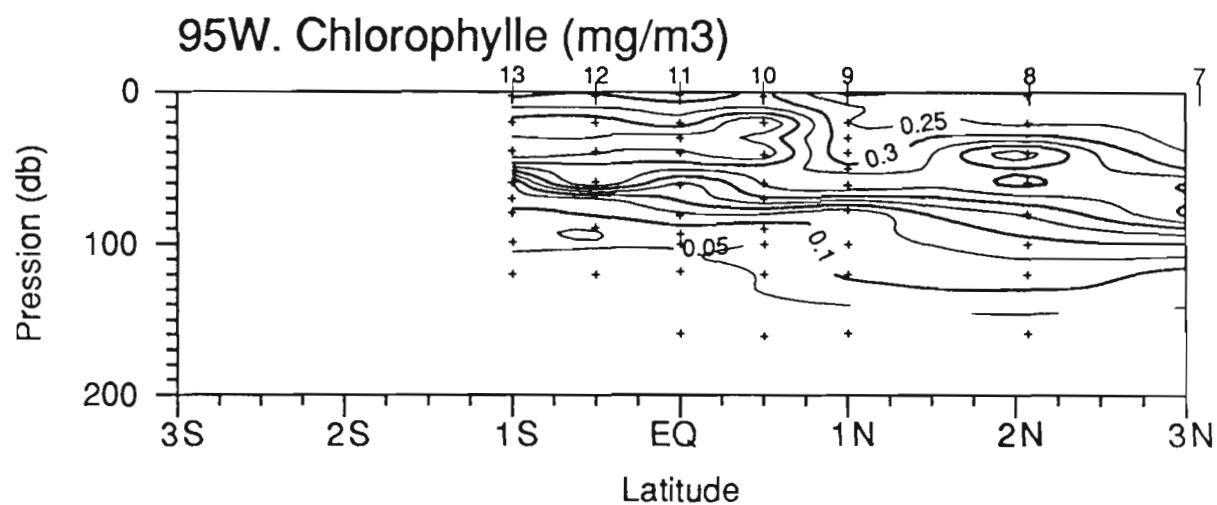

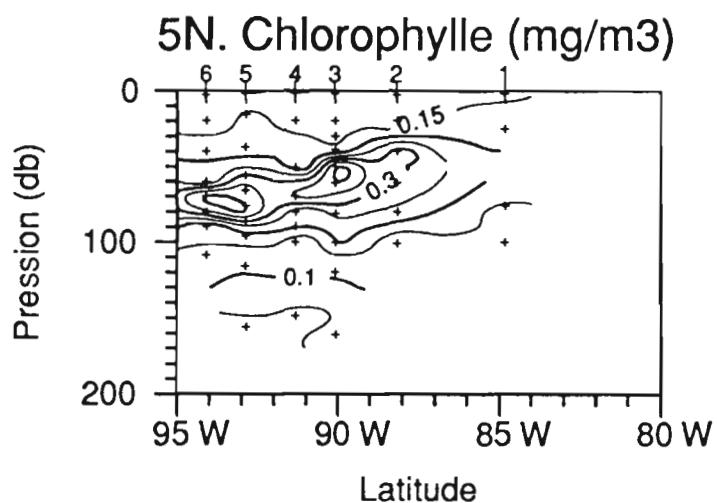

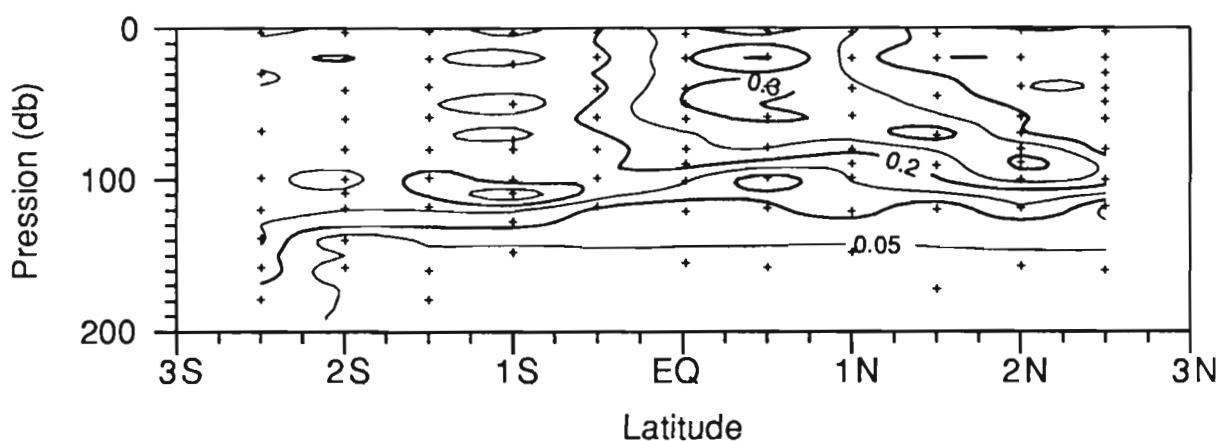

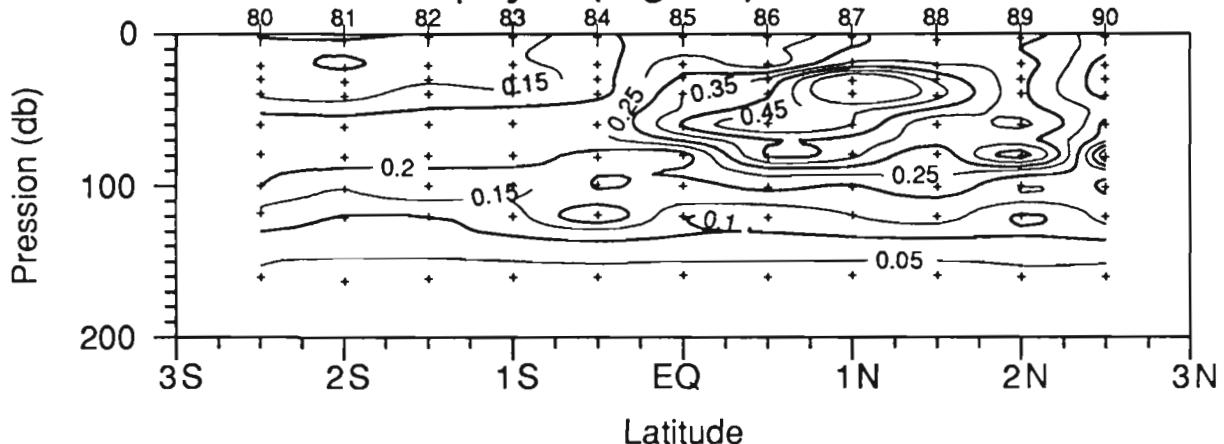

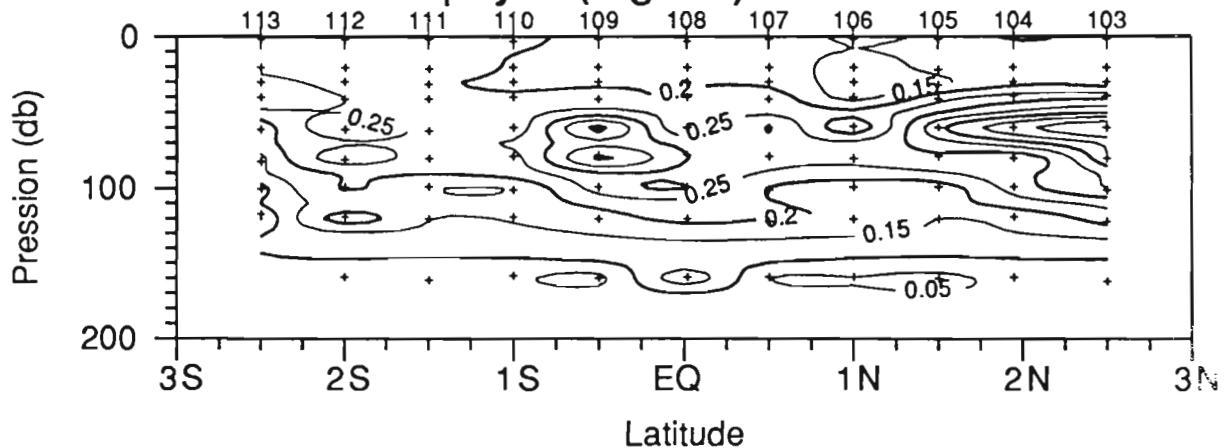

140W. Chlorophylle (mg/m³)

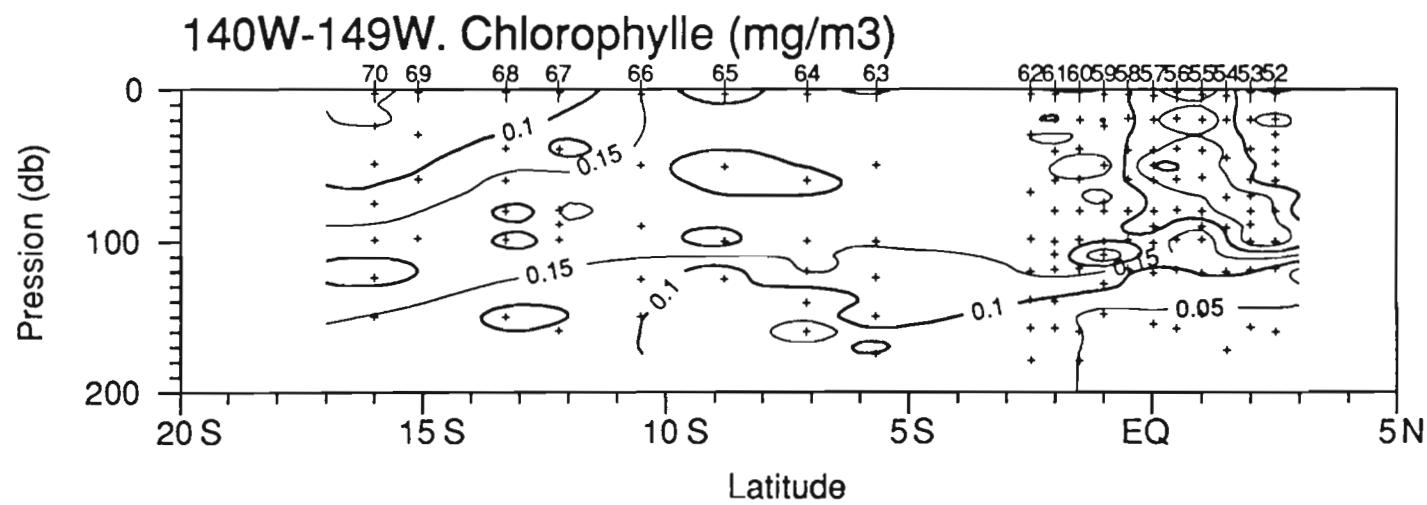

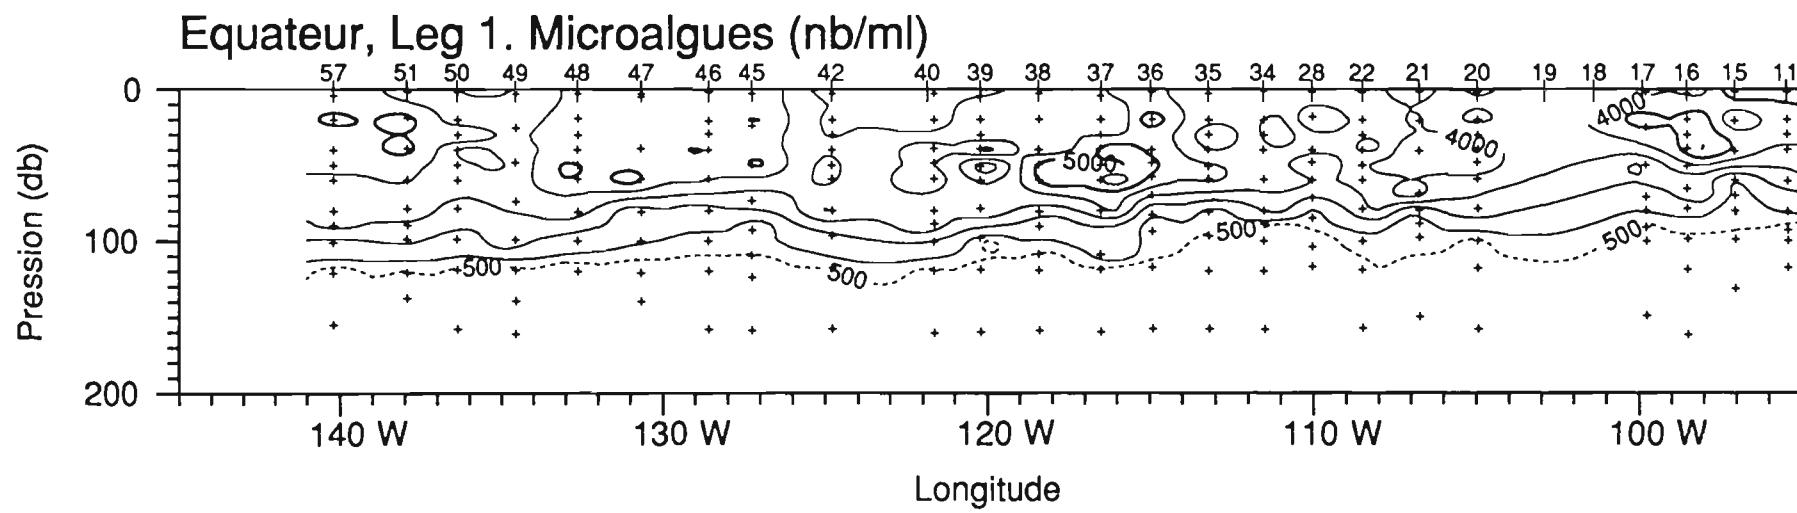

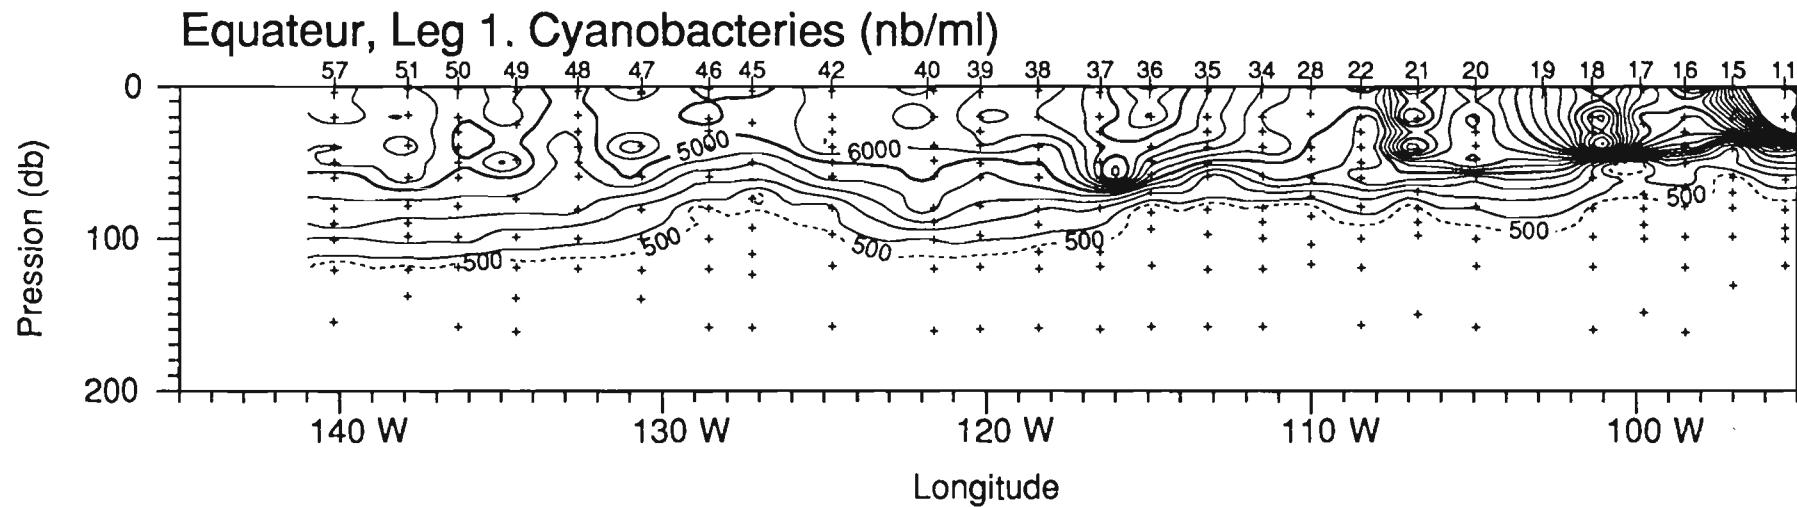

168W. Chlorophylle (mg/m³)

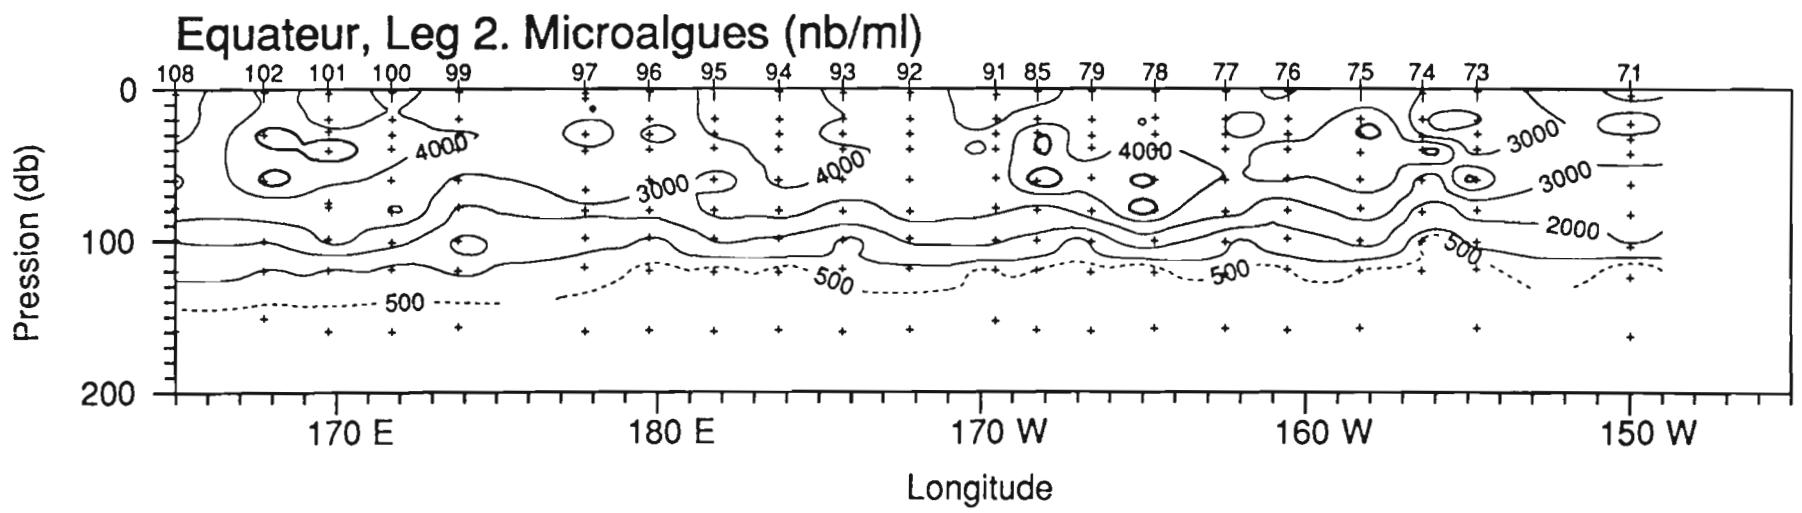

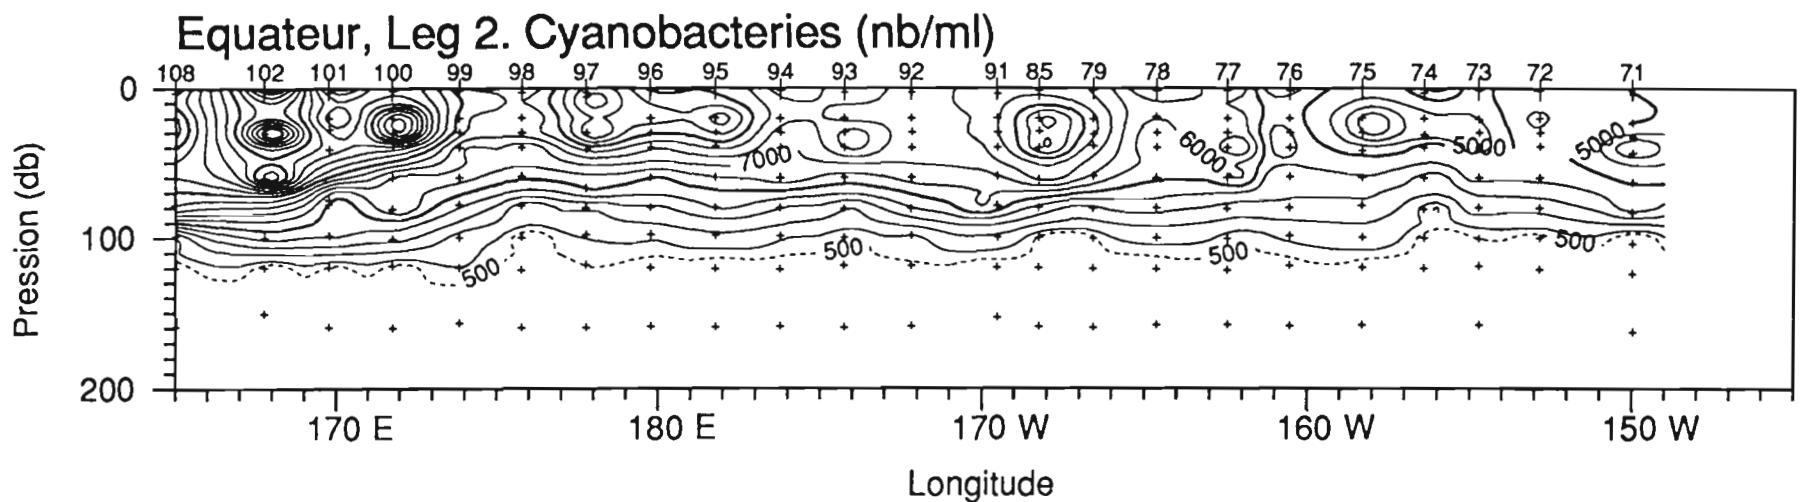

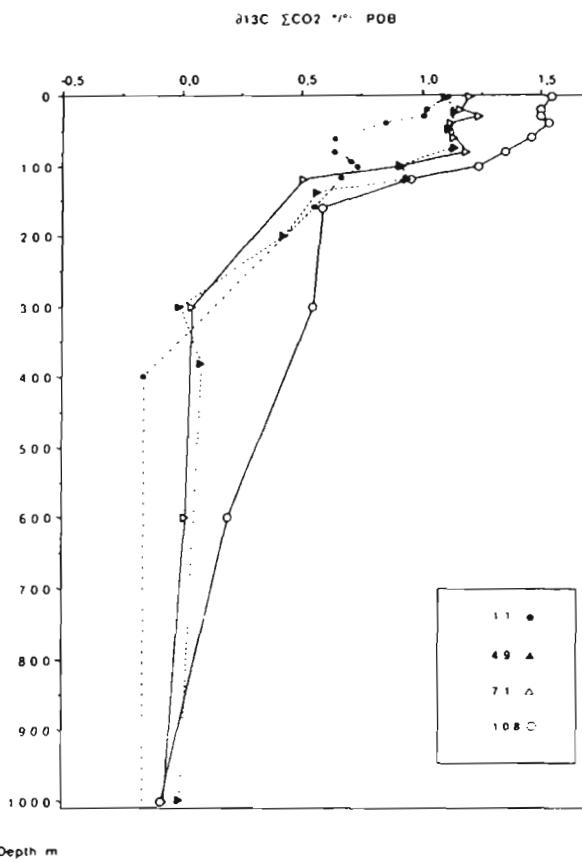

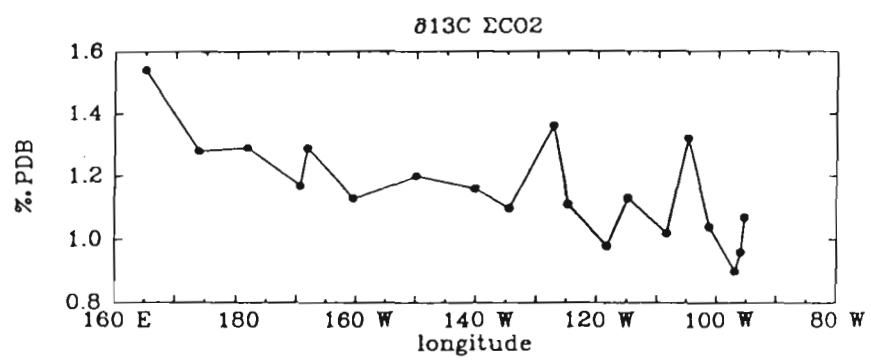

165E. Chlorophylle (mg/m³)

ANNEXE 4

Résultats détaillés des stations hydrologiques

Pour chaque station hydrologique de la campagne sont présentés:

- la liste des valeurs des mesures aux niveaux de prélèvements¹.
- 4 diagrammes utilisant les données bathysonde:

- distribution verticale θ , S, O₂, σ_θ
- diagramme S/O₂
- diagramme θ /S
- diagramme θ /O₂

¹ Les niveaux marqués * correspondent à une température de descente de la bathysonde et une salinité bathysonde ajustée à celle du prélèvement. Les niveaux marqués ** correspondent à des températures et salinités de la bathysonde à la montée.
